CERTIFICATE

This is to certify that the research work presented in this thesis entitled "**Synthesis, Characterization, Density Functional Theory and Biological Evaluation of Metal Complexes of New Ligands Derived from 2-aminonicotinaldehyde**" submitted by **Mr. Konakanchi Ramaiah** for the degree of Doctor of Philosophy in Chemistry, National Institute of Technology, Warangal (Telangana), under my supervision and that the same has not been submitted elsewhere for a degree or diploma.

Date: 17. 9. 2019

Place:

Prof. K. Laxma Reddy

Thesis Supervisor

ACKNOWLEDGEMENTS

The work presented in this thesis would not have been possible without my close association with many people. I take this opportunity to extend my sincere gratitude and appreciation to all those who made this Ph. D., thesis possible.

It gives me immense pleasure and delight to express my deep sense of gratitude to my research supervisor **Dr. K. Laxma Reddy**, Professor, Department of Chemistry, National Institute of Technology, Warangal for his inspiring and valuable guidance. His unfailing attention, unmitigated encouragement and co-operation have helped me in attaining my goal. It would have been impossible to achieve this goal without his able support and valuable advice. I consider myself fortunate that he has given me a decisive tune, a significant acceleration to my career. I will be thankful to him throughout my lifetime.

I am greatly indebted to **Prof. N. V. Ramana Rao**, Director, National Institute of Technology, Warangal allowing me to submit my research work in the form of a thesis. I express my gratitude to **Prof. T. Srinivasa Rao** and **Prof. G. R. C. Reddy**, former Directors, National Institute of Technology, Warangal for giving me the opportunity to carry out the research work.

My special words of thanks to **Prof. P. V. Srilakshmi**, Head, Department of Chemistry and **Prof. K. V. Gobi, Prof. V. Rajeswar Rao, Prof. B. Rajitha**, former Heads, Department of Chemistry, National Institute of Technology, Warangal for their valuable advice, help and support.

I express my sincere thanks to the Doctoral Scrutiny Committee (DSC) members, **Prof. A. Ramachandraiah, Prof. P. Nageswara Rao**, Department of Chemistry and **Prof. G. V. S. Nageswara Rao**, Department of Metallurgical & Materials Engineering for their valuable suggestions, motivation and care.

I take this opportunity to express thanks to **Prof. B. Venkata Appa Rao, Prof. G. V. P. Chandramouli, Prof. I. Ajit Kumar Reddy, Dr. Vishnu Shanker, Dr. Venkatathri Narayanan, Dr. D. Kashinath, Dr. K. Hari Prasad, Dr. Raghu Chitta, Dr. S. Nagarajan, Dr. M. Raghavendra, Dr. C. Jugun Prakash and Dr. Ravinder Pawar** for their suggestions and encouragement.

Financial assistance from the Government of India, Ministry of Human Resource Development (**MHRD**) in the form of fellowship is gratefully acknowledged.

I thank my research god **Dr. M. Ramachary** for all the chemistry, punctuality, sincerity and humanity I have learned from him. I thank him very much for helping me to grow as a better individual.

I sincerely thank **Dr. K. Shravankumar** and **Dr. J. Prashanth**, Kakatiya University Warangal, for their encouragement and suggestions. I thank all **my Teachers**, right from pre-school to till date for their dedicated efforts in moulding me up to this level.

My heartfelt thanks go to **Dr. J. Haribabu**, **Mr. K. N. Anees Rahman**, **Mrs. G. Rohini**, National Institute of Technology, Trichy.

My special thanks to **Dr. Y. Narsimha Reddy**, Professor, Department of Pharmacology & Toxicology, Pharmaceutical Sciences, Kakatiya University for evaluating anticancer and antioxidant activity and antimicrobial activity.

I am thankful to **Dr. G. Dhurgaiah** Department of Pharmacology & Toxicology, Pharmaceutical Sciences, Kakatiya University for his interest in the work and kind help getting the compounds assayed for biological activity.

I am sincerely thankful to all my M.Sc. batch mates, seniors and juniors, for their endless love, help, respect and support.

Cheers to my research mates who made my days at the departments memorable, **Mr. M. Saikumar**, **Mr. T. Sanjeeva**, **Dr. N. V. Bhart**, **Mr. V. Sunil Kumar**, **Dr. B. Thirupaiah**, **Mrs. N. manjula**, **Dr. G. Ramesh**, **Mr. P. Vinay**, **Dr. M. Venkanna**, **Mr. T. Dhanunjay Rao**, **Dr. K. Vimal Kumar**, **Dr. L. Suresh**, **Dr. P. Sagar Vijay Kumar**, **Mr. G. Ambedhkar**, **Mr. G. Srinath**, **Mr. G. Sripal Reddy**, **Mrs. B. Sowmya**, **Dr. B. Janardhan**, **N. Satyanarayana**, **Ms. K. Sujatha**, **Mr. P. Babji**, **Mr. Ch. Suman**, **Mrs. A. Rajini**, **Mrs. B. Mayuri**, **Dr. V. Krishnaiah**, **Dr. V. Ravi Babu**, **Mr. A. Naveen Reddy**, **Mr. Ch. Raju**, **Mr. K. Vijendar reddy**, **Mr. P. Mahendranath**, **Dr. B. Rajitha**, **Dr. M. Satyanarayana**, **Dr. M. Narsimha Reddy**, **Dr. P. Sreenu**, **Dr. K. Koteswara Reddy**, **Dr. T. Surender**, **Dr. T. Ramesh**, **Dr. G. Srinivasa Rao**, **Dr. A. Ajay Kumar**, **Dr. R. Rajkumar**, **Dr. T. Surendar**, **Dr. B. Santosh Kumar**, **Mr. A. Bhargava Sai**, **Mr. R. Venkatesh**, **Mr. S. Suresh**, **Mr. K. Shekar**, **Mr M. Srikanth**, **Mr. K. Satish**, **Mr. J. Parameswara chary**, **Mrs. Hithavani**, **Ms. G. Sivaparvathi**, **Ms. M. Sirisha**, **Mr. P. Venkatesham**, **Mrs. B. Sravanthi**.

Above all, I praise my mother **Mrs. K. Dhanamma** and my brother **Mr. K. Kamesh** for providing me the opportunity to carry out the doctoral research and their love and support. I also wish to extend my thankfulness to my family members **Mrs. D. Jyothi, Mr. D. Saidulu, Mrs. K. Sindhura, Mr. B. Nagaraju, Mrs. B. Manjusri, Mr. T. Lingaiah, Mrs. T. Padma, Mr. T. Gopi Kiran, Mrs. T. Navya, Ms. D. Kavya, Mr. D. Srinivas, Mr. T. Karunakar, K. Varshitha, K. Srujan and B. Vishnupriya** for their kindness.

Above all I pray and thank my lovable father **Mr. K. Venkateswarlu** for giving me strength for completing my higher studies successfully and dedicate this thesis in his remembrance.

I sincerely appreciate the untiring assistance rendered by my wife **Smt. K. Navya** and son **K. Jishank Varma** for their constant support, cooperation, encouragement, inspiration, love and affection whose blessings made the journey worth effort. I owe everything to them.

Besides these, several people have knowingly or unknowingly helped me for the successful completion of the thesis. I express my apology that I could not mention the names of all of them.

Konakanchi Ramaiah

CHAPTER-I

INTRODUCTION

1.1 Introduction to coordination chemistry

The probability of synthesizing a chelating agent showing absolute specificity is, no doubt, remote; however, innovative research has been and is being undertaken towards this end with other functional groups like hydroxyl, acetyl, thiol, etc. several compounds have proved to be potential chelating agents. With ever increasing knowledge of the properties of functional groups and the nature of the donor atoms to the central atom, more selective and more sensitive reagents are required constantly. The involvement of different functional group moieties with the metal ion in different orientations with a specific coordination number in the complexes have occurred. This ensures different electronic probabilities to their biological and DNA binding, docking studies, NLO properties and bacteriostatic, anticancer activities and other physico-chemical properties of these compounds.

Transition metal complexes have been part of the extensive study because of their chemical and physical properties and a wide range of applications in numerous scientific areas [1-3]. The coordination chemistry of transition metals is a complex function which involves numerous variables. Understanding and forecasting the results of the interactions involving transition metal is a prime goal in inorganic chemistry. Metal coordination complex compounds have a vast variety of technological and industrial applications ranging from catalysis and sensors to anticancer drugs. In such compounds, the metal ion has various roles, based on its coordination number, oxidation state, magnetic moment and electronic properties. However, Schiff bases are a dominant class of ligands in coordination chemistry and their complexing ability containing different donor atoms are widely explored [4-6]. The branch of medicinal inorganic chemistry is considered to have evolved with the discovery of anticancer properties of cisplatin. Thus the application of inorganic chemistry to medicine is a rapidly developing field and novel therapeutic and diagnostic of metal complexes are now exercising a positive impact on medicinal practice [7]. With the newly emerging fields of science i.e. genetic engineering, molecular biology, cell biology, nanoscience, biotechnology, magnetic resonance imaging bioinformatics etc., and the recognition of drug receptor theory, drug development programmes have been considerably boosted. The intellectual ability of the chemist plays a pivotal role in the development of new bioactive molecules. The primary task of the chemist is to prepare specific new molecules that can lead more efficiently to useful drug discovery.

Trace quantities of cobalt are essential for living organisms, including humans. Having 0.11 to 0.32 mg per kg of cobalt in soils remarkably enhances the health of grazing animals. Cobalt is a central component of cobalamin vitamin commonly known as vitamin B₁₂. Although cobalt proteins are less common than proteins containing metals like manganese, iron, or zinc, several are known. Most proteins utilize a cofactor based on the corrin cobalt, deduced from vitamin B₁₂, but there are also some proteins in which cobalt is directly coordinated by the protein structure; Methionine aminopeptidase-2 and Nitrile hydrase are two examples [8]. Cobalt compounds are known to have some synergic effect on certain antibiotics notably penicillin and they are electro active species and work as an active pharmaceutical agent in many of the drug molecules. Nickel is used in many industrial and consumer products. It plays numerous roles in the biology of microorganisms and plants [9]. Urease contains nickel as active site and the NiFe-hydrogenases which can characteristically oxidise H₂ are found to have nickel site in addition to iron-sulfur clusters. A nickel-tetrapyrrole coenzyme, F430, is present in the methyl coenzyme M reductase which powers methanogenic archaea. One of the carbon monoxide dehydrogenase enzymes consists of Fe-Ni-S cluster [10]. Other nickel containing enzymes include a class of superoxide dismutase and glyoxalase. Coordination compounds based on nickel ions are also of great interest in the field of catalysis as they are electrochemically active and can exist even in +4 oxidation state. Copper compounds are known in several oxidation states, usually +2, where they often impart blue or green colours to natural minerals such as turquoise and have been used widely as pigments. Copper(II) ion is soluble in water and at low concentration, it exhibits bacteriostatic and fungicidal activity. At lower concentrations, Cu(II) is an essential trace nutrient to all higher plant and animal life. In animals, including humans, it is found widely in tissues, with a concentration in liver, muscle and bone. It functions as a co-factor in various enzymes and in copper-based pigments. A normal human being has copper at a level of about 1.4 to 2.1 mg/kg of body weight. Copper is found in a variety of enzymes, including copper centers of cytochrome c oxidase and the enzyme superoxide dismutase (containing copper and zinc). Redox active copper is used for biological electron transport in addition to its enzymatic roles. Blue copper proteins that participate in electron transport include azurin and plastocyanin. Due to its role in facilitating iron uptake, copper deficiency can very often result in anemia like symptoms. In humans, the symptoms of Wilson's disease are caused by accumulation of copper in body tissues.

Zinc is an essential trace element, necessary for plants [11], animals [12] and microorganism [13]. Zinc is found in nearly 100 specific enzymes, serves as structural ions in transcription factors and is stored and transferred in metallothioneins. It is the second most abundant transition metal in organisms after iron and it is the only metal which appears in all enzyme classes [8]. In proteins, zinc ions are often coordinated to the amino acid side chains of aspartic acid, glutamic acid, cysteine and histidine [14]. In humans, zinc plays ubiquitous biological roles [15].

1.2 General chemistry of metals

1.2.1 Co(II) complexes

The Co(II) ion having an electronic configuration $[\text{Ar}]3\text{d}^7$ is best known for the formation of complexes with octahedral and tetrahedral geometries [16]. In an octahedral geometry, the ground state can be either $^4\text{T}_{1g}$ corresponding to the high spin state $(\text{t}_{2g})^5(\text{e}_g)^2$ or $^2\text{E}_g$, corresponding to low spin state $(\text{t}_{2g})^6(\text{e}_g)^1$. The complexes with $^2\text{E}_g$ ground term require very high Dq value and only strong field ligands such as cyanides would fulfill this requirement. In tetrahedral geometry, the only possible ground term is $^4\text{A}_2$ corresponding to the configuration $(\text{e})^4(\text{t}_2)^3$.

Co(II) forms tetrahedral complexes more readily than any other transitional metal ion, because of the small difference in stability between octahedral and tetrahedral Co(II) complexes. There are many cases where the two geometries with the same ligand are known and may be in equilibrium. Octahedral complexes are usually pale red or purple colour while tetrahedral ones are intense blue in colour.

The electronic spectra of Co(II) in its various geometries are well known and several generalizations can be made from the Orgel and Tanabe-Sugano diagrams. Gaseous Co(II) ion possesses the terms ^4F , ^4P and ^2G and under the influence of a crystal field, the ground term ^4F and the excited term ^4P split into $^4\text{T}_{1g}(\text{F})$, $^4\text{T}_{2g}(\text{F})$, $^4\text{A}_{2g}(\text{F})$ and $^4\text{T}_{1g}(\text{P})$, respectively. A schematic diagram of energy level splitting of Co(II) ion in octahedral and tetrahedral fields is given in Fig. 1.1.

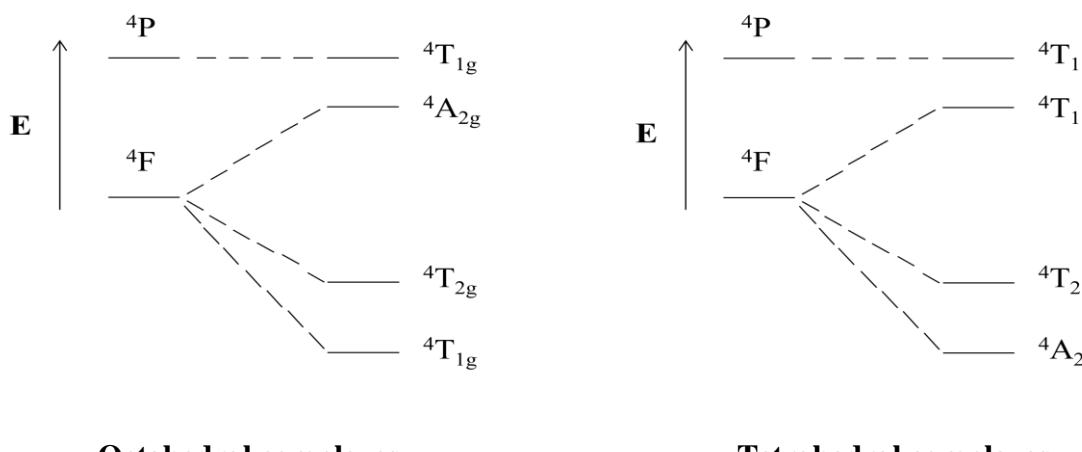

Fig. 1.1 Energy level splitting of Co(II).

Another excited term ^2G located just a little higher than ^4P is also split under the influence of a crystal field, one of the split components being $^2\text{E}_\text{g}$ state. As seen from the energy level diagram given by Tanabe and Sugano [17], $^2\text{E}_\text{g}$ crosses all the quarter levels on its way down and gives spin-forbidden transitions.

The visible absorption spectrum of octahedral Co(II) complex was explained by Abragam and Pryce [18]. According to them, the spectrum of pink $[\text{Co}(\text{H}_2\text{O})_6]^{2+}$ shows bands at 8350, 17850 and 20000 cm^{-1} which are assigned to $^4\text{T}_{1\text{g}}(\text{F}) \rightarrow ^4\text{T}_{2\text{g}}(\text{F})$, $^4\text{T}_{1\text{g}}(\text{F}) \rightarrow ^4\text{A}_{2\text{g}}(\text{F})$ and $^4\text{T}_{1\text{g}}(\text{F}) \rightarrow ^4\text{T}_{1\text{g}}(\text{P})$ transitions, respectively. Similar results were reported by Ballhausen and Jorgenson [19] for $[\text{Co}(\text{NH}_3)_6]^{2+}$ and $[\text{Co}(\text{en})_3]^{2+}$ complexes.

Tetrahedral complexes are formed usually with halides, an example being blue $[\text{CoCl}_4]^{2-}$. For these complexes the ground term is $^4\text{A}_2$ and they also show three bands in the region around 3000-5000, 6000-10000 and 15000-20000 cm^{-1} assignable to $^4\text{A}_2(\text{F}) \rightarrow ^4\text{T}_2(\text{F})$, $^4\text{A}_2(\text{F}) \rightarrow ^4\text{T}_1(\text{F})$ and $^4\text{A}_2(\text{F}) \rightarrow ^4\text{T}_1(\text{P})$, respectively [20]. But in most of the complexes, the first band, the one with lowest energy, has not been observed much.

Square-planar Co(II) complexes are very scarce in literature. A few complexes with this geometry have been reported with bis(salicylal)ethylenediamine, phthalocyanines, porphyrins, etc. [21,22].

1.2.2 Ni(II) complexes

Ni(II) ion with an electronic configuration $[\text{Ar}]3\text{d}^8$ is well known for the formation of complexes with six coordinate octahedral and four coordinate square-planar

and tetrahedral geometries. Five coordinate complexes of Ni(II) are also known but these are less stable than six and four coordinate complexes.

Octahedral Ni(II) complexes are most common and the ground state of Ni(II) in the coordination is $^3A_{2g}$ corresponding to the configuration $(t_{2g})^6 (eg)^2$. These complexes possess Russel-Saunders term 3F , 1D , 3P , 1G and 1S in the order of increasing energy. Under the influence of a cubic field the ground term 3F and excite term 3P undergoes splitting and transforms into $^3A_{2g}$, $^3T_{2g}$, $^3T_{1g}(F)$ and $^3T_{1g}(P)$. The next excited term 1G also splits, one of the split components being 1E_g state which gives spin-forbidden transitions.

The Ni(II) with coordination number six can form complexes of regular or distorted octahedral stereochemistry. In regular octahedral complexes, three spin allowed transitions viz. $^3A_{2g}(F) \rightarrow ^3T_{2g}(F)$, $^3A_{2g}(F) \rightarrow ^3T_{1g}(F)$ and $^3A_{2g}(F) \rightarrow ^3T_{1g}(P)$ are expected and they generally fall within the ranges 7000-13000, 11000-20000 and 19000-27000 cm^{-1} , respectively. In addition, some spin-forbidden transitions are also observed for $[\text{Ni}(\text{H}_2\text{O})_6]^{2+}$, the three spin allowed transitions in the order given are found at 8500, 13500 and 25300 cm^{-1} and for $[\text{Ni}(\text{NH}_3)_6]^{2+}$ they are found at 10700, 17500 and 28200 cm^{-1} [23,24]. The energy separation between $^3A_{2g}(F)$ and $^3T_{2g}(F)$ is equal to 10 Dq and the values of 10 Dq in octahedral Ni(II) complexes vary between 6400 and 12700 cm^{-1} , depending on the position of the ligand in the spectrochemical series [25]. In distorted octahedral complexes, more transitions are expected owing to the further splitting of $^3T_{1g}$ and $^3T_{2g}$ states [26,27].

Tetrahedral Ni(II) complexes have the same Russel-Saunders terms as the octahedral ones giving rise to 3T_1 ground term. The best example of tetrahedral complexes are Ni(II) halides studied by Furlani and Morpurgo [28], Goodgame et al. [29] and Boston and Smith et al. [30]. Thus, three bands are observed in the ranges 4000, 7500 and 14000-16000 cm^{-1} which may be assigned respectively to $^3T_1(F) \rightarrow ^3T_2(F)$ (ϑ_1), $^3T_1(F) \rightarrow ^3A_2(F)$ (ϑ_2) and $^3T_1(F) \rightarrow ^3T_{1g}(P)$ (ϑ_3). Also, some spin-forbidden bands are observed [28-30] in the ranges 11000, 11600 and 20000 cm^{-1} , respectively.

The electronic ground state of square-planar Ni(II) complex may be either $(eg)^4$ ($^1A_{1g}$) 2 (b_{2g}) 2 with a spin-singlet term $^1A_{1g}$ or $(eg)^4$ (a_{1g}) 2 (b_{2g}) 1 (b_{1g}) 1 with a spin-triplet term $^3A_{2g}$. The relative stability of the $^1A_{1g}$ and $^3A_{2g}$ states is determined by the energy separation (ϑ_1) between d_{xy} and $d_{x^2-y^2}$ orbitals. Ballhausen and Liehr [27] have shown that

low-spin state is more stable, the separation between the two being more than 10000 cm^{-1} . According to Maki [26], the only possible ground state is $^1\text{A}_{1g}$ which suggests that all Ni(II) square-planar complexes are diamagnetic. For these complexes, generally one to three bands are observed around 15000 , 20000 and 25000 cm^{-1} due to $^1\text{A}_{1g}(\text{D}) \rightarrow ^1\text{A}_{2g}(\text{G})$, $^1\text{A}_{1g}(\text{D}) \rightarrow ^1\text{B}_{2g}(\text{G})$ and $^1\text{A}_{1g}(\text{D}) \rightarrow ^1\text{E}_g(\text{G})$, respectively [26]. Square-planar complexes by the absence of d-d transition below 10000 cm^{-1} in the former as a consequence of large crystal field splitting. Tanabe-Sugano diagram of octahedral Ni(II) complex as shown in Fig. 1.2.

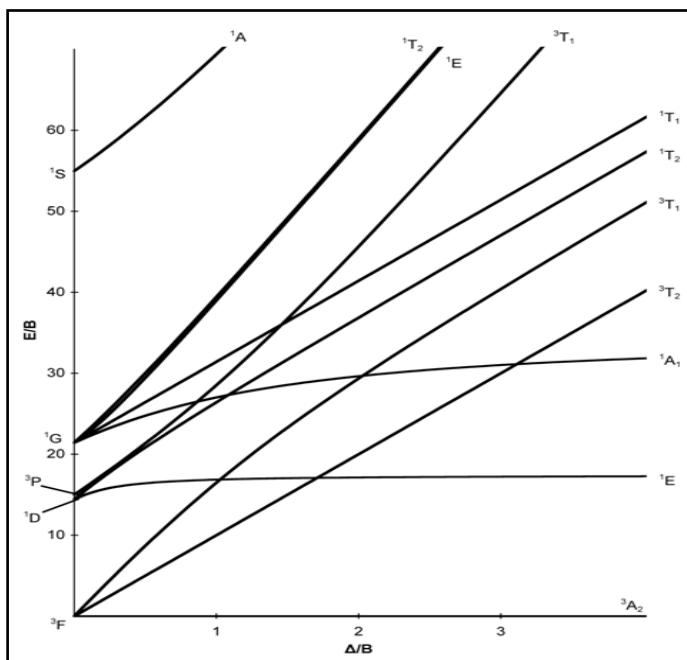

Fig. 1.2 Tanabe-Sugano diagram of octahedral Ni(II) complex.

1.2.3 Cu(II) complexes

The Cu(II) ion having an electronic configuration $[\text{Ar}]3\text{d}^9$ forms complexes of octahedral, tetrahedral and square-planar geometries with a variety of ligands. It also forms trigonal bipyramidal and square pyramidal complexes, the latter ones being more common [31]. The ground state in octahedral and tetrahedral geometries is orbitally degenerate and since the unsymmetric d^9 configuration is prone to Jahn-Teller distortion, the regular octahedral and the regular tetrahedral complexes of Cu(II) complexes is distorted (elongated) octahedron, involving four short in-plane equatorial bonds and two long axial bonds.

These complexes with octahedral, tetrahedral or square-planar geometry possess only one Russel-Saunders term ^2D and there is no other term in higher energy. This term

splits in octahedral geometry giving 2E_g ground state and $^2T_{2g}$ excited state and thus only a single transition is expected [32]. But in distorted octahedral or tetragonal complexes 2E_g will split into two components $^2B_{1g}$, $^2A_{1g}$ and $^2T_{2g}$ into two other components $^2B_{2g}$ and 2E_g . Therefore, the following three transitions are expected $^2B_{1g} \rightarrow ^2A_{1g}$, $^2B_{1g} \rightarrow ^2B_{2g}$ and $^2B_{1g} \rightarrow ^2E_g$, respectively as shown in Fig. 1.3.

Similar to tetragonal geometry, the ground term in square-planar geometry is $^2B_{1g}$, the excited terms being $^2A_{1g}$, $^2B_{2g}$ and 2E_g , the three transitions are expected here as well. The d-d bands of square-planar Cu(II) complexes are observed in the range 14000-25000 cm^{-1} [33,34]. However, the electronic spectra provide no much information in distinguishing between planar and tetragonal Cu(II) complexes.

In tetrahedral fields also, the term 2D will split into two terms giving 2T_2 as the ground term and 2E as the excited term. Crystal field theory predicts again for true tetrahedral complexes only one transition $^2T_2 \rightarrow ^2E$ which occurs below at 10000 cm^{-1} . In distorted tetrahedral complexes, the ground and excited terms undergo further splitting and as a result, four transitions are expected. However, Sacconi and Ciampolini [35] have reported only three bands at 8500, 13600 and 21000 cm^{-1} in the case of salicylidene aminato Cu(II) complex and assigned them to a pseudo tetrahedral geometry. Octahedral and square-planar Cu(II) complexes have been extensively studied by ESR technique. However, only a few tetrahedral Cu(II) complexes have been subjected to this study. The complete theory for the ESR of Cu(II) complexes have been given by Abraham and Pryce [36] and others [37,38]. Maki and McGarvey [39] and later Kivelson and Neiman derived expressions for the metal-ligand bonding and orbital reduction parameters employing molecular orbital theory.

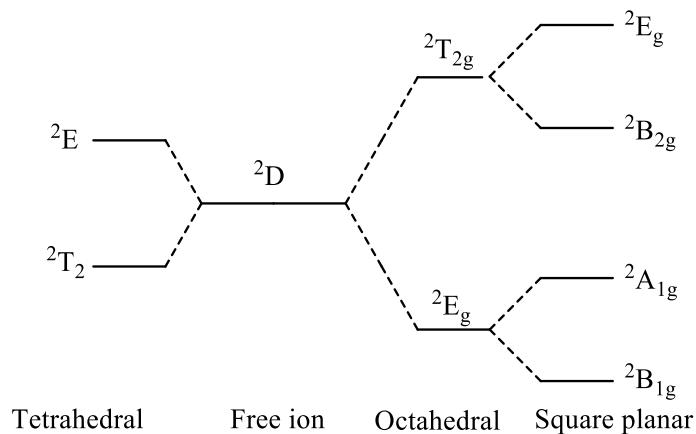

Fig. 1.3 Energy level splitting of Cu(II) complexes.

1.2.4 Zn(II) complexes

Zn(II) ion with the electronic configuration [Ar]3d¹⁰ forms numerous complexes of tetrahedral e.g. [Zn(NH₃)₂Cl₂], octahedral e.g. [Zn(Py)₃Cl₂] and square pyramidal geometry e.g. aquobis(8-hydroxyquinoline)-Zn(II) stereochemistry and amongst these, the complexes of tetrahedral geometry are predominant. The stereochemical differences of the complexes formed by Zn(II) ion result from the ligand conformation and packing considerations owing to the fact that the ion has a completed d shell (d¹⁰) and is, thus, devoid of ligand field stabilization energy effects. Square-planar geometry is less common for Zn(II) complexes; however, a few cases of four coordinate square-planar complexes are known, for example, bis(glycyl)zinc(II) [40].

Biologically, Zn(II) is one of the most important metal ions and it is an essential constituent of several enzymes e.g. carboxypeptidase. In plants, Zn(II) is a constituent of the enzyme carbonic anhydrase, a catalyst involved in the conversion of carbon dioxide into carbonic acid [41]. Zn(II) also plays an important role in the production of insulin.

1.2.5 Pd(II) complexes

The metal palladium with the electronic configuration [Kr]4d⁸ forms complexes with various ligands in different oxidation states such as zero, two and four.

Pd(0) generally forms tetrahedral complexes which are diamagnetic. These complexes show a single broad absorption around 25000 cm⁻¹, which may be due to intraligand transition since in a d¹⁰ system no d-d transition is expected.

Pd(II) mostly forms square-planar complexes which are, as expected, diamagnetic. Pd(II) complexes possessing paramagnetic behaviour are very rare. The electronic ground term for a diamagnetic square-planar Pd(II) complex is ¹A_{1g}, which is derived from ¹D term symbol. Three peaks are usually observed for Pd(II) square-planar complexes in the visible region around 15000, 20000 and 25000 cm⁻¹ which may be assigned to the spin-allowed transitions ¹A_{1g} → ¹A_{2g}, ¹A_{1g} → ¹B_{1g} and ¹A_{1g} → ¹E_g, respectively [42].

Pd(II) forms octahedral complexes which are also diamagnetic. These show a medium intensity peak at 25000 cm⁻¹ due to intraligand transition and a very weak peak due to spin-forbidden ¹A_{1g} → ¹T_{1g} transition [43].

1.3 General aspects of the ligand systems used in the present study

The ligand systems used in the present study is the molecule, 2-aminonicotinaldehyde (ANA), a basic unit and the compounds derived from it, so a brief account of the general aspects of these compounds is presented.

1.3.1 2-aminonicotinaldehyde and its derivatives

In recent years, modern coordination chemistry has expanded its horizons to emerging areas of metal organic frameworks [44-47], crystal engineering [48], non-linear optical materials [49-53], therapeutic [54,55], catalytic activity studies [56-58] and other areas of interdisciplinary research. Several classes of ligand architectures have been developed over the ages to suit appropriate applications. One such class of ligands with scarce literature citations are *o*-aminoaldehydes. Historically, *o*-aminoaldehydes have often been employed as important building blocks for several pharmaceutically relevant compounds like naphthyridine derivatives (for Osteoporosis) [59], plant-antitumor agents (Camptothecin-Analogues) [60], antihistamine [61] and pain relieving agents (mGlu5 receptor antagonist) [62], etc., shown in Fig. 1.4.

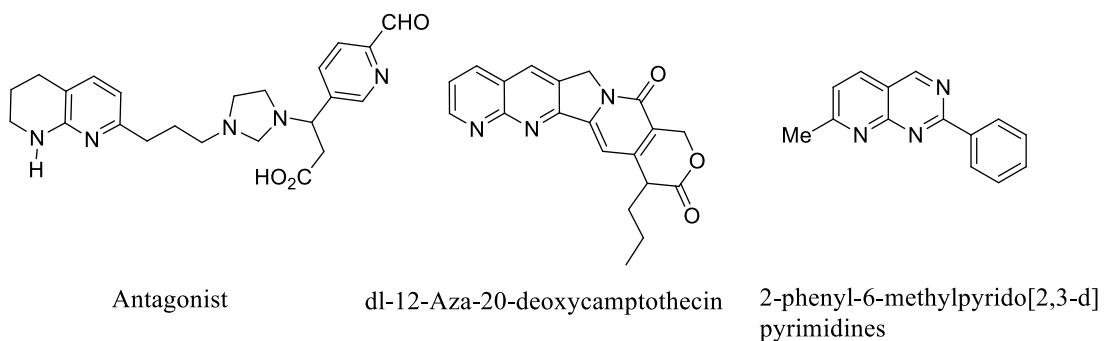

Fig. 1.4 Application of *o*-aminoaldehydes as synthetic building blocks for pharmaceutical applications

2-aminonicotinaldehydes are widely used to prepare other organic compounds in industry and for enabling biological activity in NLO materials and polymers. Similar to *o*-aminobenzaldehyde, 2-aminonicotinaldehyde, though heterocyclic compounds show some aromatic as well as some aliphatic properties, on the whole, the compounds and its derivatives predominantly show aromatic pyridine ring, aldehyde on one hand and amine on the other. An excellent account of these compounds and their applications in different fields are discussed in the literature. These compounds exhibit spectral properties owing to the functional groups present in them. The structural characterization of these

compounds has been established by different analytical techniques so as to select as ligands in the present study.

In the present investigations, we have used 2-aminonicotinaldehyde having aldehyde and amine groups, which condense to form Schiff bases. From a synthetic point of view, ligands like ANA and its Schiff bases have been explored and extensively studied. 2-aminonicotinaldehyde has three coordination sites out of which prominent pyridines ring N atom, N of NH₂ group and O of CHO. Schiff base derivatives are conspicuous in addition to azomethine N atom and other functional group N, O and S donor atoms in the complexes for denticity.

Moreover, the process of coordination/chelation plays a significant role in biological systems [63,64]. Literature studies suggest that the biological activity of many compounds used as drugs is enhanced by chelation with the metal ion [65].

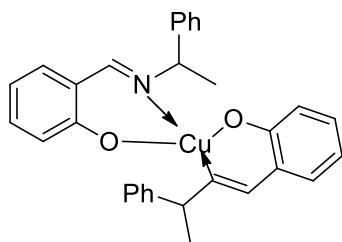

1.4 Use of Schiff bases and their metal complexes

Schiff bases and their metal complexes command significant attention because of their biological activities including antibacterial, antifungal, anti-tumor, nematocide, antiphlogistic antidepressants, anti-carcinogenic and catalytic activity [66,67]. Schiff base metal complexes are also used in different applications such as molecular docking and density functional theory.

1.4.1 Schiff base metal complexes as catalysts

Schiff's bases are able to coordinate metals through azomethine nitrogen and there is a wide use of these metal complexes as catalysts. Many Schiff base complexes show excellent catalytic activity in various reactions and in the presence of moisture. Over the past few years, there have been many reports on their applications in homogeneous and heterogeneous catalysis. The high thermal and moisture stabilities of many Schiff base complexes were useful attributes for their application as catalysts in reactions involving high temperatures.

In 1968, Noyori *et al.* [68] developed a Cu(II) Schiff base complex for the metal carbenoid cyclopropanation of styrene, one of the first ligand used for asymmetric catalysis.

Schiff's base complexes of metals including Ni(II), Fe(II), Mn(II), Ru(III) Cr(III), etc. have been used as catalysts for epoxidation of olefins and as mono oxygen sources for catalyst to carry out oxygen transfer to the olefins [69,70].

Schiff base transition metal complexes are used as catalyst in several reactions such as oxidation of organic compounds, hydrosilylation of ketones, Henry reaction, aldol reaction, epoxidation of alkenes, reduction of thionyl chloride, reduction reaction of ketones, polymerization reaction, synthesis of bis(indolyl) methanes and Diels-Alder reaction etc.

Mn(II) complex having triazole structure act as a useful catalyst [71] for the Henry reaction and form hydroxy nitroalkanes in good yield. Fe(III), Co(II) and Ru(III) complexes derived from hydroxyl benzaldehyde are used as effective catalysts in oxidation of cyclohexane into cyclohexanol and cyclohexanone in presence of hydrogen peroxide [72].

Fehring *et al.* [73] reported that Schiff base complexes of transition metals were effective catalysts in carrying out asymmetric reduction of dialkyl ketones to alcohols. Catalytic property of dioxomolybdenum(VI) Schiff base complexes for the oxidation of alcohols with H_2O_2 as an oxidant were described by Ngan *et al.* [74].

On observing and making note of the above results, 2-aminonicotinaldehyde containing metal complexes were used as catalyst by using multicomponent reaction.

1.4.2 Multicomponent reaction (MCR)

MCRs are prominent synthetic tools that allow minimum of three components in a one-pot reaction to obtain diverse polyfunctional drug-like scaffolds through the formation of several covalent bonds between carbon-carbon and carbon heteroatoms. In these reactions, most of the starting materials are retained and the isolation of intermediate is not required. The significant advantages of MCRs are high atom economy, efficiency, mild conditions, high convergence or divergence, library generation, the easier progress of the reaction, decreased reaction times, high selectivity, etc. [75-89]. Because

of the variation of substituents, skeleton and stereochemistry, diversity was achieved in MCR approach [90]. Based on the reactivity concept, MCRs can be divided into three different categories. In domino-type MCRs, all reagents have to be present from the very beginning of the process. The subsequent addition of components in a well-defined order without changing the reaction conditions is known as sequential MCR. Finally, the consecutive MCR implements the subsequent addition of reagents by changing the conditions from step to step [91]. The formation of cyanohydrins, imines, first described by Gerhard and Laurent in 1838, can be considered as the first multicomponent reaction. After that, several methods like Strecker synthesis, Hantzsch reaction, Biginelli reaction, Mannich reaction, the Passerini reaction, Ugi reaction etc. were developed [92]. At present using catalyzed MCRs is a common practice to synthesize a variety of heterocycles and heteroatomic organic compounds. In line with these precedents, the use of zinc based catalysts (homogeneous/heterogeneous) and reagents would be a good choice to meet the requirements of green chemistry. We are interested in developing a facile MCR protocol to synthesize pyranopyrazoles or substituted pyridines in view of the imaginative applications in medicinal and materials chemistry.

1.4.3 Theoretical applications

1.4.3.1 Computational chemistry

There are two approaches for designing compounds and understanding their properties in the perspective of applications; a) computational approach and b) experimental approach. Computational science is principally concerned with the numerical calculation of molecular interactions and molecular electronic structures. The term computational chemistry is more often used when a mathematical system is sufficiently well developed for automatic implementation on a computer. Experimental chemistry on the other hand offers analytical expressions for the properties of molecules and their reactions. Two of the important areas of study using computational chemistry are i) Designing new compounds with required properties by molecular modeling, ii) quantum mechanical studies of experimentally synthesized compounds.

Molecular properties such as total energy, charges, surface area volume, reactivity, dipole moment, polarizability, vibrational frequencies or other spectroscopic properties can be predicted. Thus, many experimental chemists are now using computational modeling to gain additional understanding of compounds being examined

in the laboratory. In view of the importance of computational chemistry to generate some of the important properties of novel compounds synthesized in the present investigation.

1.4.3.2 Molecular docking studies

The major application of molecular docking studies is in the design of compounds *in silico* which are targeted against proteins, the binding modes of these compounds (ligands) attaching themselves to active site of a target protein. Thus the compounds which are strongly bound to a protein were treated as lead molecules. In *in vitro* experiments, drugs are discovered by chance in a trial-and-error method by using high-throughput screening of a large number of compounds against a given target. This process is time consuming and highly expensive. On the other hand, if the 3D structure of the compound is known, the molecular docking is a useful tool in the identification of drug candidates by virtual screening of compound databases. The energetically more favourable ligand conformation is suitable for docking. In general, low energy scores represent better protein-ligand bindings [93]. The most commonly used heuristic search algorithms that have been applied to molecular docking are simulated annealing and evolutionary algorithms [94-98].

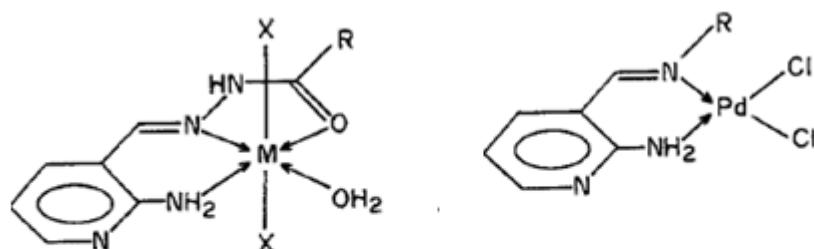

1.5 Survey of literature on 2-aminonicotinaldehyde and their metal complexes

Metal complexes of Schiff bases have occupied a central role in the development of coordination chemistry. This is manifested by a large number of publications ranging from the purely synthetic to modern physicochemical to biochemically relevant studies of these complexes. A variety of stable compounds containing both transition and non transition metals and multifarious ligands have been synthesized and studied. In many cases, the stereochemistry, electronic structures and properties of these complexes have been reasonably understood.

A detailed literature search on the coordination chemistry of ANA and its Schiff base metal complexes, only a few reports are available. In the following paragraphs are presented survey of literature concerning the synthesis and structural characterization of metal complexes of Schiff bases derived from 2-aminonicotinaldehyde.

Bodige Swamy and Jagannatham Swamy prepared [99] stable metal complexes of Cu(II), Ni(II), Co(II), Zn(II) and Pd(II) with mixed Schiff base ligands derived from 2-aminonicotinaldehyde and benzoic acid hydrazides (Benzoic acid, *p*-toluic acid and *p*-chlorobenzoic). The compounds have been characterized by physicochemical data.

Co(II), Ni(II), Cu(II) and Zn(II) complexes have been assigned for octahedral geometry and square-planar geometry for Pd(II) complexes.

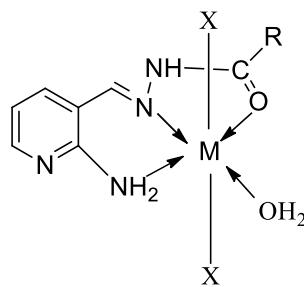

R = Ph or p-MeC₆H₄ or PClC₆H₄. X = Cl, Br. M = Co(II), Ni(II), Cu(II) and Zn(II).

Dasharatham *et al.* [100] reported novel compounds of N,N'-bis(2-aminonicotinalidene)-1,2-ethanediamine (**1**), N,N'-bis(2-aminonicotinalidene)-1,2-phenylenediamine (**2**), N,N'-bis(2-aminonicotinalidene)-1,2-phenylenediamine (**3**) and N,N'-bis(2-aminonicotinalidene)-1,3-propanediamine (**4**) and their Co(II) complexes derived from 2-aminonicotinaldehyde. The compounds are characterized by different spectroscopic techniques, and ligand **2** was confirmed by single crystal X-ray data. The ligands act as neutral quadridentate and form square-planar type complexes. All the Cu(II) complexes are stable and non-electrolytes in nature. These complexes also act as potential precursors for the synthesis of macrocyclic compounds.

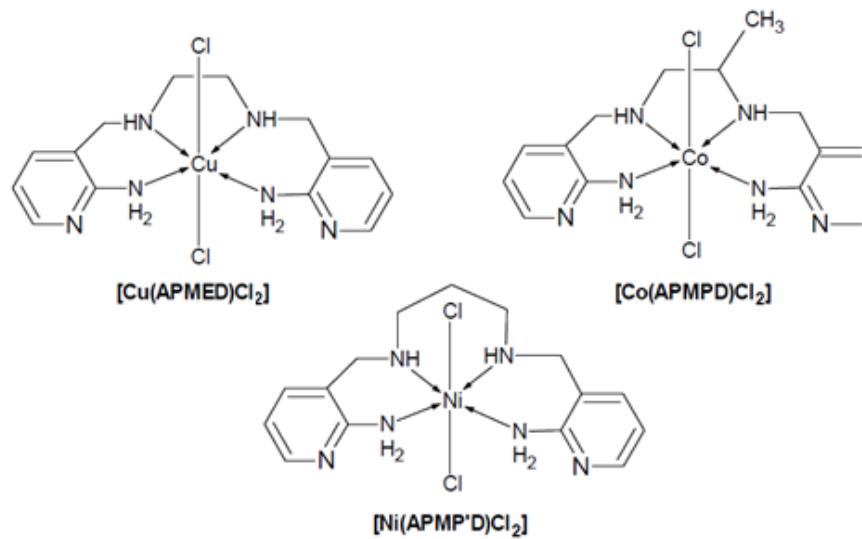

Khamamkar *et al.* [101] reported the synthesis and characterization of Mn(II), Co(II), Ni(II), Cu(II), Zn(II) and Cd(II) complexes with Schiff base ligand *E*-2-((2-amino pyridine-3-yl) methylene amino)ethane thiol derived from 2-aminonicotinaldehyde and cysteamine. The ligand acts as neutral, bidentate with N and S donor atoms assigned octahedral geometry for Mn(II), Co(II), Cu(II), Zn(II) and Cd(II), Tetrahedral for Ni(II). The antibacterial activity of Co(II) and Ni(II) complexes exhibited potent activity.

Swamy *et al.* [102] carried out the synthesis and characterization of Ni(II), Co(II), Zn(II), Cu(II) and Cd(II) complexes with acetic acid and phenyl acetic acid hydrazones. The compounds were confirmed using different techniques like elemental analysis, electronic, IR, magnetic moment, molar conductance, thermal and ESR spectral studies. The complexes have been assigned for octahedral geometry.

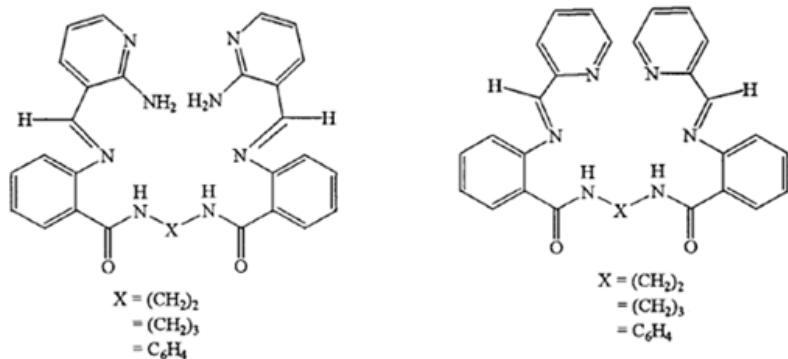

$M = \text{Co(II)}, \text{Ni(II)}, \text{Cu(II)}, \text{Zn(II)} \text{ and } \text{Cd(II)}$. $X = \text{Cl/Br}$, $R = \text{CH}_3/\text{CH}_2\text{-C}_6\text{H}_5$.

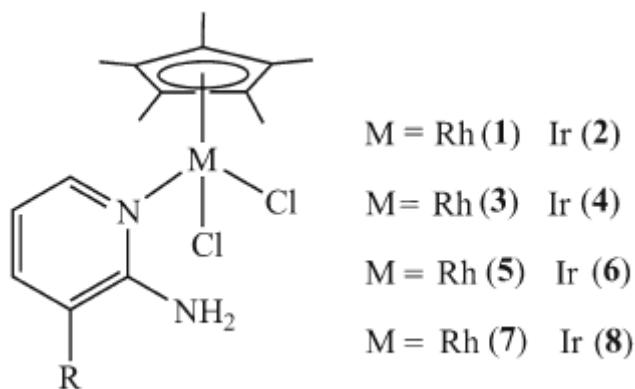

Jyothi *et al.* [103] described the synthesis and characterization of Co(II), Ni(II), Cu(II) and Zn(II) complexes with Schiff bases obtained by the condensation of 2-aminopyridine-3-carbaldehyde with 1,2-diaminoethane (APMED)/ 1,2-diaminopropane (APMPD)/1,3-diaminopropane (APMP'D)/*trans*-cyclohexane-1,2-diamine. The complexes have been characterized by NMR, IR, Electronic and ESR spectral studies. All the complexes have octahedral geometry holding 0-6 water molecules in the lattice with general molecular formula $[\text{MLCl}_2] \cdot n \text{ H}_2\text{O}$. These complexes were reported to show excellent non-linear optical properties.

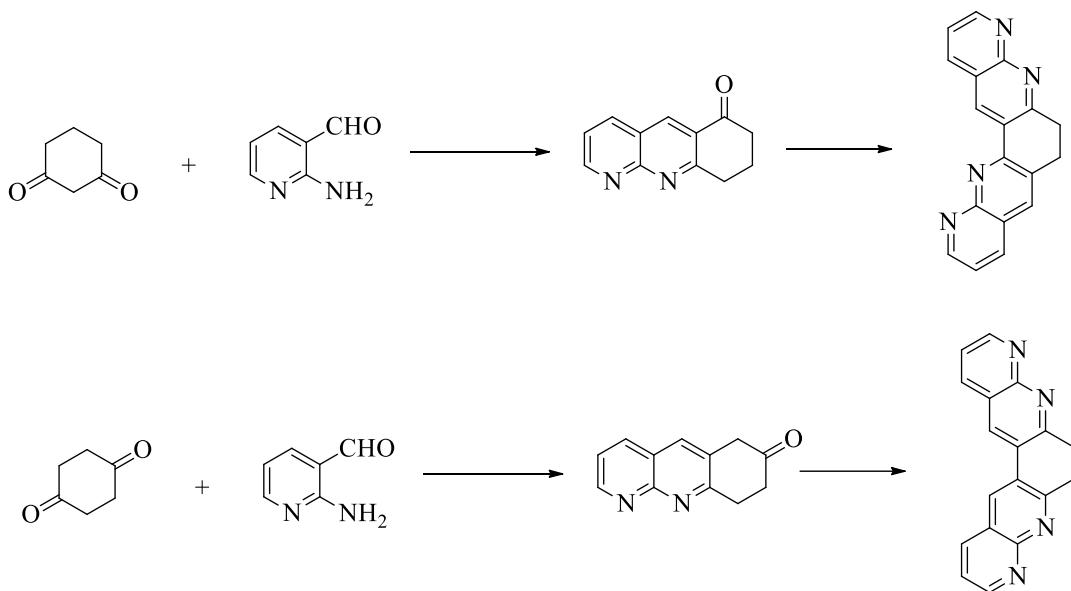

Swamy *et al.* [104] reported that hexadentate ligands derive from 2-aminonicotinaldehyde. The compounds are characterized by elemental analysis and IR spectroscopic techniques.

Kalidasan *et al.* [105] have reported new Schiff base complexes $[\text{Cp}^*\text{MCl}_2(\text{L})]$ [where $\text{M} = \text{Rh, Ir}$; $\text{L}1 = 2\text{-amino-3-picoline}$, $\text{L}2 = 2\text{-amino-3-nicotinopyridine}$, $\text{L}3 = 2\text{-amino-3-pyridine carboxyaldehyde}$ and $\text{L}4 = 2\text{-aminopyridine}$. The complexes are confirmed by single crystal X-ray diffraction studies.

Majewicz *et al.* [106] described the reaction pyridine analog of 2-aminonicotinaldehyde with cyclic aliphatic diketones (1,3-diketocyclohexane) yields fused polypyridyl ligands which have been extensively used to prepare polymetallic complexes having interesting magnetic properties.

Application of 2-aminonicotinaldehyde for the synthesis of fused polypyridyl ligands

Metal binding affinities of *o*-aminoaldehydes have not been extensively studied. Eichhorn and co-workers have reported Cu(II) complexes of *o*-aminobenzaldehyde. Preliminary spectral characterization revealed a di-copper complex [107].

Equipped with the knowledge of biological and optical importance of ANA, we set out to explore the coordination properties of ANA and ANA containing Schiff base ligands with metals like Co(II), Ni(II), Cu(II), Zn(II), Cd(II) and Pd(II).

1.6 Objectives of the present work

Metal complexes of a wide variety of organic ligands have significantly contributed to the development of modern coordination chemistry. Among the forerunners of organic ligands are heterocyclic compounds and their derivatives, with a particular reference to 2-aminonicotinaldehyde which are generally Schiff bases. These derivatives and their metal complexes have received much attention by researchers mainly because of their synthetic feasibility, bonding variability, structural diversity, catalytic capability and varied bioactivity [108].

2-aminonicotinaldehyde and its Schiff base ligands have acquired a great deal of interest because of their potentially ambidentate nature and pharmacological applications. These ligands bind to a metal ion in a variety of bonding modes along with a monodentate *N*-pyridine ligand in addition to bidentate ligand and these compounds play an important role in biology. Metal complexes of these ligands have exhibited antibacterial, anti-

fungal, anticancer, ROS, antioxidant and anti-inflammatory activities as indicated by recent literature [109-111].

Considering the importance associated with this class of compound, the author has considered it worthwhile to undertake the synthesis, characterization, biological evaluation and theoretic studies of metal complexes by different new 2-aminonicotinaldehyde containing Schiff base ligands. The studies have been also extended by testing the catalytic applications of the metal complexes for the synthesis of fully substituted pyridines and dihydropyrano[2,3-*c*]pyrazoles.

CHAPTER-II

EXPERIMENTAL

2.1 Preparation of the ligands

2.1.1 Synthesis of 2-aminonicotinaldehyde (ANA)

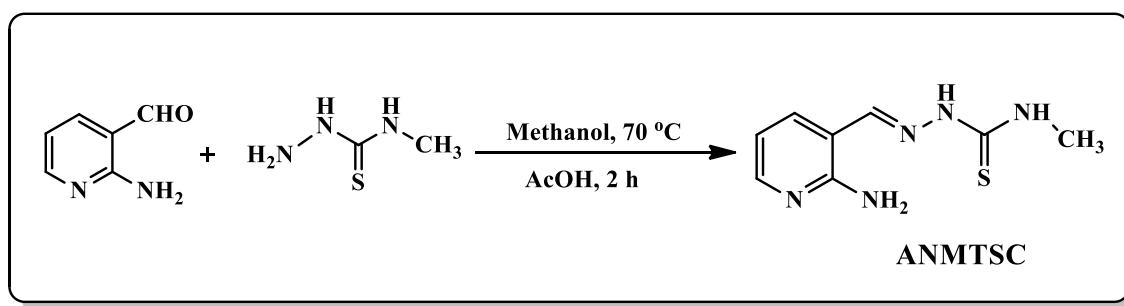

A mixture of nicotinamide (36.5 g) and ammonium sulphamate (52.0 g) was heated in an oil bath at 150 °C. After a clear melt was obtained, the temperature was raised slowly to 200 °C. The mixture was kept at this temperature for 6 h after which the contents of flask had completely solidified. Water was added and the precipitate obtained was filtered and washed with ether. This was refluxed in 2N HCl for 4 h, made alkaline and extracted with ether. This resulting ether solution was dried over K_2CO_3 and evaporated to give pure 2-aminonicotinaldehyde. It was recrystallized from benzene to give yellow crystals suitable for X-ray diffraction. Yield: 40%. M.p.: 99 °C. Anal. Calcd. for $\text{C}_6\text{H}_6\text{N}_2\text{O}$ (%): C, 58.95; H, 4.91; N, 22.93. Found: C, 58.80; H, 4.80; N, 22.87. FT-IR (KBr): ν , cm^{-1} 3414 ($\nu_{(\text{N-H})}$), 1667 ($\nu_{(\text{C=O})}$), 1590 ($\nu_{(\text{C=N})}$ (Py)). ^1H NMR (400 MHz, $\text{DMSO}-d_6$): δ , ppm 9.84 (s, 1H, CHO), 8.24 (d, J = 8.0 Hz, 1H, Ar-H), 8.00 (d, J = 8.0 Hz, 1H, Ar-H), 7.55 (s, 2H, -NH₂), 6.72-6.75 (m, 1H, Ar-H). ^{13}C NMR (100 MHz, $\text{DMSO}-d_6$): δ , ppm 194.12 (CHO), 158.70, 155.36, 145.02, 113.44, 112.69 (Aromatic carbons).

2.1.2 Synthesis of 2-aminonicotinaldehyde *N*-methyl thiosemicarbazone (ANMTSC)

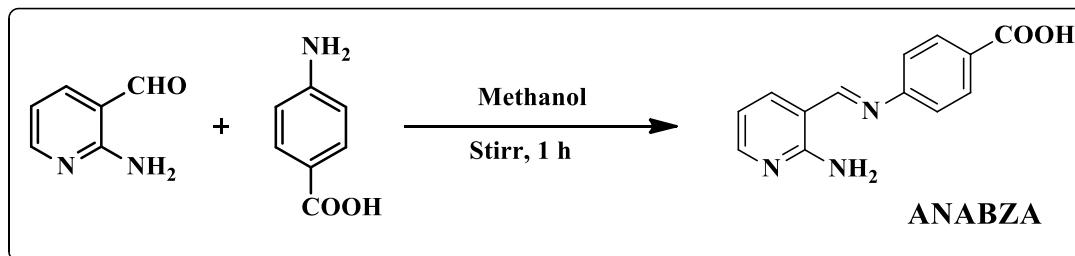

ANMTSC ligand was prepared by refluxing 4-methyl-3-thiosemicarbazide (1.05 g, 10 mmol) with 2-aminonicotinaldehyde (1.22 g, 10 mmol) in 50 mL of methanol for 2 h in the presence of glacial acetic acid (4-5 drops). During this time, yellow coloured compound was obtained, the product was filtered and washed with cold methanol and dried in *vacuum*. The compound was recrystallized in DMF-DCM (1:3) to get pure product. Yield: 90%. M.p.: 245 °C. Anal. Calcd. for $\text{C}_8\text{H}_{11}\text{N}_5\text{S}$ (%): C, 45.91; H, 5.30; N,

33.47; S, 15.32. Found: C, 45.88; H, 5.28; N, 33.42; S, 15.30. FT-IR (KBr): ν , cm^{-1} 3413, 3315, 3180 (N–H), 1557 (C=N), 1272 (C=S). ^1H NMR (400 MHz, DMSO- d_6): δ , ppm 11.23 (s, 1H, NH), 8.38 (q, J = 3.6 Hz, 1H, terminal NH), 8.15 (s, 1H, HC=N), 8.00 (d, J = 7.3 Hz, 1H, aromatic-H), 7.49 (d, J = 7.5 Hz, 1H, aromatic-H), 6.98 (s, 2H, NH₂), 6.66-6.55 (m, 1H, aromatic-H), 3.01 (d, J = 3.8 Hz, 3H, terminal CH₃). ^{13}C NMR (100 MHz, DMSO- d_6): δ , ppm 177.5 (C=S), 156.6 (C=N), 149.8, 145.7, 140.8, 112.4, 110.7 (aromatic carbons), 31.6 (methyl carbon).

2.1.3 Synthesis of 4-(2-aminopyridin-3-methylene)aminobenzoic acid (ANABZA)

A mixture of 2-aminonicotinaldehyde (1.22 g, 10 mmol) and 4-aminobenzoic acid (1.37 g, 10 mmol) in methanol was stirred for 1 h, to obtain a yellow color precipitate. The product was collected by filtration, washed with methanol and dried in a desiccator over calcium chloride. Yield: 95%. M.p.: 270-272 °C. Anal. Calcd. for C₁₃H₁₁N₃O₂ (%): C, 64.72; H, 4.60; N, 17.42. Found: C, 64.65; H, 4.56; N, 17.48. FT-IR (KBr): ν , cm^{-1} 3420 (N–H), 1629 (C=N), 1567 (C=N)_{py}, 1701 (C=O)_{carboxylic acid}. ^1H NMR (400 MHz, DMSO- d_6): δ , ppm 12.93 (s, 1H, OH), 8.72 (s, 1H, CH=N), 8.14 (d, J = 6.0 Hz, 1H, aromatic-H), 8.00-7.87 (m, 5H, aromatic-H), 7.38 (s, 2H, NH₂), 6.72-6.69 (m, 1H, aromatic-H). ^{13}C NMR (100 MHz, DMSO- d_6): δ , ppm 167.49, 163.88, 158.44, 155.10, 152.18, 143.40, 131.11, 128.37, 121.77, 112.46, 112.34.

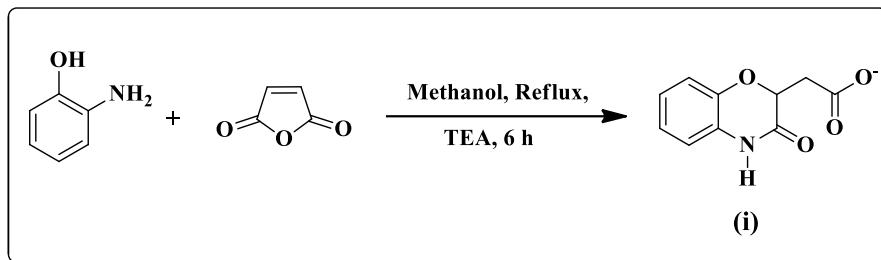

2.1.4 Synthesis of 2-aminonicotinaldehyde benzoxazinonyl acetic acid hydrazone (ABAH)

This compound was prepared in three steps:

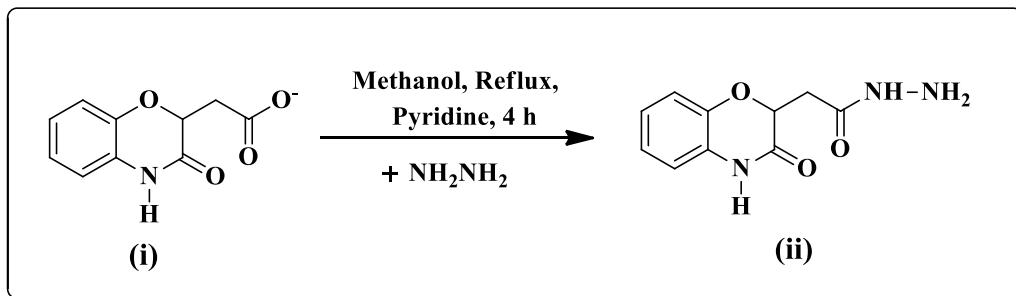

(i) (3,4-dihydro-3-oxo-2H-1,4-benzoxazin-2-yl)-acetate

A mixture of 2-aminophenol (5.45 g, 0.05 mol) and maleic anhydride (4.9 g, 0.05 mol) were dissolved in methanol containing 3.25 mL of triethylamine. The contents of the flask were refluxed for 6 h. The solution was removed in *vacuo* and the residual semisolid mass poured into crushed ice while stirring. The compound that separated out was filtered, washed several times with cold water and methanol to give a white compound. Yield: 89%. M.p.: 143-145 °C. Anal. Calcd. for $C_{10}H_8NO_4^-$ (%): C, 58.25; H, 3.91; N, 6.79; O, 31.04. Found: C, 58.02; H, 3.87; N, 6.46; O, 30.94.

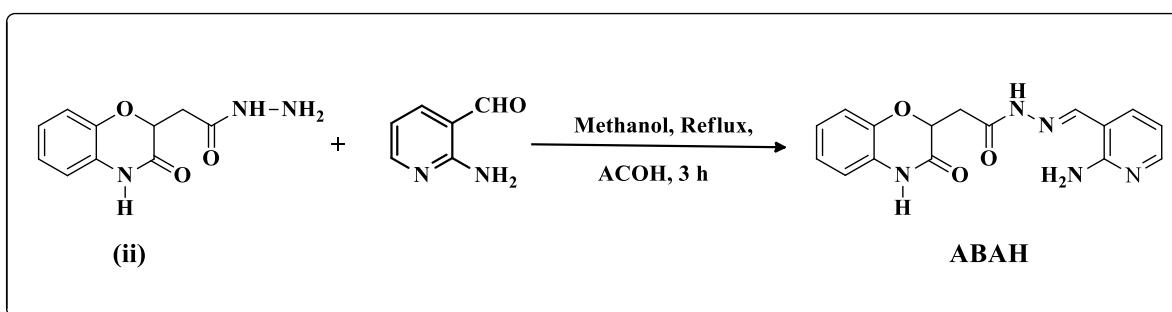

(ii) (3,4-Dihydro-3-oxo-2H-1,4-benzoxazin-2-yl) acetic acid hydrazide

11.05 g (0.05 mol) of compound (i) was dissolved in methanol and to this 3.75 mL of hydrazine hydrate was added gradually with stirring. The two solutions were refluxed for 4 h during the course of which 1-2 drops of pyridine was added. The reaction mixture was reduced to half its volume and cooled to get white solid. The product was filtered, washed with water and methanol. Yield: 87%. M.p.: 208-210 °C. Anal. Calcd. for $C_{13}H_{11}N_3O_2$ (%): C, 54.29; H, 5.01; N, 19.00; O, 21.70. Found: C, 54.05; H, 4.90; N, 18.82; O, 21.50.

(iii) 2-Aminonicotinaldehyde benzoxazinonyl acetic acid hydrazone (ABAH)

5.52 g (0.025 mol) of compound (ii) was taken in a minimum amount of methanol. This was added gradually to another solution containing 3.05 g (0.025 mol) of 2-aminonicotinaldehyde in 10 mL of methanol under stirring in the presence of acetic acid (2 drops). The reaction mixture was refluxed for 3 h when a light yellow compound separated out. This was filtered and washed with methanol to get pure light yellow colored compound. Yield: 87%. M.p.: 257-259 °C. Anal. Calcd. for $C_{13}H_{11}N_3O_2$ (%): C, 59.08; H, 4.65; N, 21.53; O, 14.75. Found: C, 59.15; H, 4.62; N, 21.35; O, 14.33. FT-IR (KBr): ν , cm^{-1} 3400 (N–H, free), 3180 (N–H, H-bonded) 1670 (C=O, ring amide), 1610 (C=N), 1570 (C=O, ali.amide). 1H NMR (400 MHz, DMSO): δ ppm 12.13 (s, 1H, cyclic - NH), 11.05 (s, 1H, CO-NH-N), 8.72 (s, 1H, CH=N), 7.39 (s, 2H, NH₂), 6.69-8.10 (M, 7H, aromatic-H), 5.02 (t, 1H, C₂H of benzoxazinone), 2.51 (d, J = 6.0 Hz, 2H, -CH₂-CO).

2.2 Preparation of the complexes

In the preparation of all the metal complexes, the metal salt and the ligand were combined in 1:2 mole ratio (the metal being in slight excess of what the ratio required) using required quantities of methanol so as to effect the solubility of the metal salts and the ligands. The general procedure adopted in the preparation of the metal complexes is given metal-wise while other synthetic details are presented in Table 1.

2.2.1 Co(II) complexes

A solution of $Co(OAc)_2 \cdot 4H_2O$ / $CoCl_2 \cdot 6H_2O$ in methanol was added drop-wise under stirring with methanolic solution of the ligand. The reaction mixture was stirred for few minutes at room temperature followed by refluxing. The resulting colored solid was filtered off, washed with methanol and dried in *vacuum* over fused $CaCl_2$.

2.2.2 Ni(II) complexes

A solution of the ligand in methanol was added slowly with stirring to $\text{Ni(OAc)}_2 \cdot 4\text{H}_2\text{O}$ / $\text{NiCl}_2 \cdot 6\text{H}_2\text{O}$ in methanol. The mixture was refluxed on a hot water bath. The solid that resulted from refluxing the mixture was filtered and then washed with water, methanol and ether after which it was dried in vacuum over CaCl_2 .

2.2.3 Cu(II) complexes

The methanolic solution of ligand and methanolic solution containing $\text{Cu(OAc)}_2 \cdot \text{H}_2\text{O}$ / CuCl_2 were mixed with constant stirring for a few hours under reflux, and then the precipitate formed was collected by filtration, washed with methanol and dried in a desiccator over calcium chloride.

2.2.4 Zn(II) complexes

$\text{ZnCl}_2 \cdot 4\text{H}_2\text{O}$ solution in methanol was added slowly under stirring with methanolic solution of the ligand. The solid that separated on refluxing the mixture on a hot water bath was filtered, washed with methanol and ether and dried at *vacuum*.

2.2.4.1 $[\text{Zn(ANA)}_2\text{Cl}_2]$ complex

^1H NMR (400 MHz, DMSO- d_6): δ , ppm 9.89 (s, 2H, -CHO), 8.28 (d, J = 8.0, 2H), 8.00 (d, J = 8.0, 2H), 7.58 (s, 4H, -NH₂), 6.73-6.76 (m, 2H). ^{13}C NMR (100 MHz, DMSO- d_6): δ , ppm 194.10, 158.68, 155.31, 145.08, 113.49, 112.69.

2.2.4.2 $[\text{Zn(ANMTSC)}_2]$ complex

^1H NMR (400 MHz, DMSO- d_6): δ , ppm 8.43 (s, 1H, terminal NH), 8.20 (s, 1H, HC=N), 8.05 (d, J = 7.2 Hz, 1H, aromatic-H), 7.56 (d, J = 6.4 Hz, 1H, aromatic-H), 7.02 (s, 2H, NH₂), 6.67 (s, 1H, aromatic-H), 3.07 (s, 3H, terminal CH₃). ^{13}C NMR (100 MHz, DMSO- d_6): δ , ppm 177.5 (C=S), 156.5 (C=N), 149.8, 145.7, 140.8, 112.4, 110.7 (aromatic carbons), 31.6 (methyl carbon).

2.2.4.3 $[\text{Zn(ANABZA)}_2\text{Cl}_2]$ complex

^1H NMR (400 MHz, DMSO- d_6): δ , ppm 12.07 (s, 1H, OH), 8.74 (s, 1H, CH=N), 8.13-7.91 (m, 6H, aromatic-H), 7.33 (s, 2H, NH₂), 6.72 (s, 1H, aromatic-H). ^{13}C NMR (100 MHz, DMSO- d_6): δ , ppm 166.98, 163.78, 157.30 154.88, 152.08, 142.96, 131.01, 129.01, 121.67, 112.42, 112.31.

2.2.5 Pd(II) complexes

A 0.1 N HCl solution of PdCl_2^* was treated with an equal volume of methanol added dropwise under stirring with a solution of the ligand in methanol. The mixture was refluxed on a hot water bath. At the end of the reaction excess methanol was removed in vacuum and filtered after cooling to obtain pure product.

[PdCl_2^* was dissolved in concentrated hydrochloric acid and diluted with water to 100 mL to give 0.1 N solution with respect to hydrochloric acid].

2.2.5.1 $[\text{Pd}(\text{ANA})_2\text{Cl}_2]$ complex

^1H NMR (400 MHz, $\text{DMSO}-d_6$): δ , ppm 9.86 (s, 2H), 8.25 (d, $J = 8.0$, 2H), 8.05 (d, $J = 8.0$, 2H), 7.64 (s, 4H, $-\text{NH}_2$), 6.76-6.79 (m, 2H). ^{13}C NMR (100 MHz, $\text{DMSO}-d_6$): δ , ppm 193.99, 158.15, 154.34, 145.68, 113.91, 112.70.

2.2.5.2 $[\text{Pd}(\text{ANMTSC})\text{Cl}_2]$ complex

^1H NMR (400 MHz, $\text{DMSO}-d_6$): δ , ppm 8.38 (s, 1H, terminal NH), 8.14 (s, 1H, $\text{HC}=\text{N}$), 7.99 (d, $J = 7.2$ Hz, 1H, aromatic-H), 7.51 (d, $J = 7.2$ Hz, 1H, aromatic-H), 6.97 (s, 2H, NH_2), 6.62 (bs, 1H, aromatic-H), 3.01 (s, 3H, terminal CH_3). ^{13}C NMR (100 MHz, $\text{DMSO}-d_6$): δ , ppm 177.5 (C-S), 156.5, 149.8, 145.6, 140.8, 112.4, 110.8 (aromatic carbons), 31.6 (methyl carbon).

2.2.5.3 $[\text{Pd}(\text{ANABZA})\text{Cl}_2]$ complex

^1H NMR (400 MHz, $\text{DMSO}-d_6$): δ , ppm 12.82 (s, 1H, OH), 8.61 (s, 1H, $\text{CH}=\text{N}$), 8.03 (d, $J = 6.0$ Hz, 1H, aromatic-H), 7.89-7.77 (m, 5H, aromatic-H), 7.28 (s, 2H, NH_2), 6.62-6.59 (m, 1H, aromatic-H). ^{13}C NMR (100 MHz, $\text{DMSO}-d_6$): δ , ppm 167.39, 163.79, 158.44, 155.00, 152.09, 143.30, 131.01, 128.27, 121.68, 112.36, 112.25.

2.2.6 Cd(II) complexes

The solution mixture consisting of $\text{CdCl}_2 \cdot \text{H}_2\text{O}$ and the ligand in methanol was refluxed on hot water bath and cooled when a solid separated. It was filtered, washed with methanol and ether in succession and was dried in vacuum over fused CaCl_2 .

2.2.6.1 $[\text{Cd}(\text{ANA})_2\text{Cl}_2]$ complex

^1H NMR (400 MHz, $\text{DMSO}-d_6$): δ , ppm 9.85 (s, 2H, $-\text{CHO}$), 8.25 (d, $J = 8.0$, 2H), 8.01 (d, $J = 8.0$, 2H), 7.55 (s, 4H, $-\text{NH}_2$), 6.73- 6.76 (m, 2H). ^{13}C NMR (100 MHz, $\text{DMSO}-d_6$): δ , ppm 194.52, 158.70, 155.340, 145.04, 113.47, 112.68.

2.2.6.2 [Cd(ANMTSC)₂] complex

¹H NMR (400 MHz, DMSO-*d*₆): δ , ppm 8.19 (s, 1H, terminal NH), 7.93 (d, *J* = 3.6 Hz, 1H, HC=N), 7.75 (d, *J* = 7.6 Hz, 1H, aromatic-H), 7.36 (d, *J* = 6.8 Hz, 1H, aromatic-H), 7.03 (s, 2H, NH₂), 6.57 (t, *J* = 6.4 Hz, 1H, aromatic-H), 3.00 (s, *J* = 3.2 Hz, 3H, terminal CH₃). ¹³C NMR (100 MHz, DMSO-*d*₆): δ , ppm 178.0 (C=S), 156.5 (C=N), 148.6, 147.0, 140.2, 112.3, 112.1 (aromatic carbons), 32.8 (methyl carbon).

2.2.6.3 [Cd(ANABZA)Cl₂] complex

¹H NMR (400 MHz, DMSO-*d*₆): δ , ppm 12.52 (s, 1H, OH), 8.22 (s, 1H, CH=N), 8.10-7.85 (m, 6H, aromatic-H), 7.85 (s, 2H, NH₂), 6.60 (s, 1H, aromatic-H). ¹³C NMR (100 MHz, DMSO-*d*₆): δ , ppm 165.28, 163.11, 155.01 153.63, 150.47, 139.65, 130.01, 127.51, 120.54, 112.83, 110.62.

2.3 Bio assay investigations

2.3.1 *In vitro* antibacterial and antifungal activity

The *in vitro* antimicrobial activity of the ligands and their metal complexes were evaluated against different gram positive bacteria (*Bacillus subtilis* and *Staphylococcus aureus*) and different gram negative bacteria such as (*Proteus vulgaris*, *Klebsiella pneumoniae*, *Pseudomonas aeruginosa* and *Escherichia coli*) and few fungal strains (*Aspergillus niger*, *Aspergillus flavus*, *Pencillium notatum*, *Curvularia lunata*, *Rhizoctonia bataticola* and *Candida albicans*) by disc diffusion method. By using Whatmann No. 1 paper, 6 mm diameter sterile antibiotic discs were placed over the nutrient agar medium. With the help of micropipette, 100 μ g/mL concentrated compounds were transferred to each disc (Initially compounds were dissolved in DMSO). Subsequently bacteria and fungi incubated overnight at 37 °C and 25 °C, respectively. The zone of inhibition values were calculated in millimeter and distinguished with standard antibiotics. DMSO was used as a negative control whereas Streptomycin 30 μ g/disc (standard antibiotic) and standard antifungal drug Ketoconazole/Nystatin (10 μ g/disc) were chosen as positive controls. All the experiments were carried out in triplicate and the average zone of inhibition was recorded and minimum inhibitory concentration (MIC) values for the tested compounds as well as standards were measured in μ g/mL.

2.3.2 DPPH free radical scavenging activity assay

The free radical scavenging activity of the newly synthesized ligands and their metal complexes were determined using DPPH (1,1-diphenyl-2-picryl hydrazyl) method [1]. According to literature [2], DPPH is a well known radical and a scavenger for other radicals, therefore, DPPH radical was reduced in the presence of antioxidant. In brief 0.2 mM solution of DPPH in 100 mL methanol was prepared. In this 3 mL of methanolic DPPH solution was added to 1 mL of ligands and their metal complexes in DMSO at different concentrations (3 μ M, 10 μ M, 30 μ M, and 100 μ M) after which the mixture was shaken vigorously and kept in dark at room temperature. After 30 min the absorbance of the test compounds was measured at 517 nm using UV-Visible spectrophotometer. Methanol was used as blank, ascorbic acid was used as standard while DPPH solution was used as control without the test compounds. The percentage of scavenging activity of DPPH free radical was measured using the following formula.

$$\text{Scavenging Activity}(\%) = \frac{A_0 - A_1}{A_0} \times 100$$

Here A_0 , is the absorbance of DPPH in the absence of an antioxidant and A_1 , is the absorbance of DPPH in the presence of an oxidant. In addition, IC₅₀ values were calculated for all the compounds.

2.3.3 *In vitro* anticancer activity

The ligands and their metal complexes were evaluated for their *in vitro* anticancer activity against different human cancer cell lines, namely HeLa (cervical), IMR-32 (neuroblastoma), A549 (lung), MCF-7 (breast), COLO-205 (colon), HepG-2 (liver), murine macrophage (Raw 264.7) and HEK293 (embryonic kidney), by comparing them with corresponding activity in the case of the standard drug cisplatin. These cancer cell lines were provided by the National Centre for Cell Sciences (NCCS), Pune, India. Cell viability in the presence of synthesized compounds were measured by MTT (3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide)-microcultured tetrazolium assay [3,4], which is a quantitative colorimetric method for the determination of cell viability. The assessed parameter is the metabolic activity of viable cells. Metabolically active cells reduce pale yellow tetrazolium salt (MTT) to a dark blue formazan, which is insoluble in water. This can be quantified directly, after solubilization with DMSO, as the absorbance of the formazan is related to the number of viable cells. HeLa, IMR-32, A549, MCF-7,

COLO-205, HepG-2 and Raw 264.7 cells were plated into a 96-well plate at a density of 1×10^4 cells/well. Cells were grown overnight in the full medium and then switched to low serum media. 1% DMSO was used as a control. After 48 h of treatment with different concentrations of test compounds, the cells were incubated with MTT (2.5 mg/mL) in the CO₂ chamber for 2 h. The medium was then removed and 100 μ L of DMSO was added into each well to dissolve formazan crystals. After thoroughly mixing, the plates were read at 570 nm for optical density, which bears direct correlation with cell quantity. The results were represented as percentage of viability. All the experiments were carried out in triplicate.

2.3.4 *In vivo* anti-inflammatory activity

Male Albino Wister rats of same age of weight around 170-220 g were selected for the present study. They were housed in polypropylene cages. They were acclimatized in the institute animal house with standard diet and water ad libitum after approval by the animal ethical committee. The animal was made to fast 18 h before the start of the experiment.

2.3.4.1 Method

Carrageenan induced rat paw edema method [5] was used to asses anti-inflammatory activity in rats. The animals were divided into three groups (n = 6). Where GP-I as a control, GP-II received a standard, Indomethacin (5 mg/kg) and GP-III was administered test compounds (10 mg/kg) orally. After 30 min, 0.1 mL of 1 % carrageenan suspension in normal saline was injected into the sub plantar region of the left hind paw of each rat to induce edema. The volume measurements were recorded using plethysmograph at intervals of 0, 1, 2, 4, and 6 h. The paw volumes of treated animals were compared with the control group and the % inhibition was calculated using the following equation.

$$\text{Percentage inhibition (\%)} = [1 - \text{volume in test (mL)}/\text{volume in control}] \times 100.$$

2.3.5 *In vivo* antidiabetic activity

2.3.5.1 Animals for the investigation

With prior acceptance number from IAEC/32/UCPSc/KU/2015, male Wister rats were bought from Mahaveer agencies, Hyderabad, India and utilized for antidiabetic

studies. In the investigation of antidiabetic study, the male Wister rats weighed around 180-240 g.

2.3.5.2 Induction of diabetes in rats

In order to induce diabetes in rats that were made to fast overnight alloxan monohydrate single intra peritoneal (i.p) injection (150 mg/kg body weight) was given, which was dissolved in saline. It is followed by 0.5 mL of 20% glucose after 3 h of Alloxan and 5% glucose solution ad libitum for next 24 h. After 72 h of alloxan injection, blood samples were taken from retro-orbital plexus of rats and measured for blood glucose levels. Only those rats with blood glucose levels of ≥ 200 mg/dl (diabetic) were chosen for the study.

2.3.6 Reactive oxygen species levels studies

Reactive oxygen species (ROS) play an important role in cancer cell death and apoptosis. In the assay of ROS, 2',7'-dichlorodihydrofluorescein diacetate (DCFH-DA) which was used as fluorescent probe gets converted to non-fluorescent probe (DCFH) by the action of intracellular esterases [6]. The non-fluorescent substrate gets oxidized by free radicals present in the cells and gives a fluorescent product of DCF. The intensity of DCF formation depends upon the amount of ROS release which indirectly quantifies the intracellular peroxides formation. So ROS measurement (Cat#: STA-342, OxiSelectTM) was used to identify ROS levels on a panel of five cell cultures. The test compounds with concentrations of (100 - 3.125 μ M) were tested on HeLa, MCF-7, A549 and IMR-32 cancer cell lines for 24 h under good cell culture practice (GCCP). All the cell lines were obtained with job number 1620 from NCCS, Pune, India. All the cell lines were subcultured in serum free medium, Roswell Park Memorial Institute (RPMI) 1640. In brief, 6×10^4 cells per well were transferred into 96 well plates followed by the addition of 100 μ L test compounds solution. After this, all the culture plates were incubated in CO₂ incubator (5% CO₂) at 37 °C (MRC.4.11.13, London, UK). The serum-free media of test metal complexes were removed and renewed with 10 μ M 2',7'-dichlorodihydrofluorescein diacetate solution. The cells were washed gently with cold PBS-EDTA 3 times. The emissions were recorded at 488/525 nm excitation and emission wavelength using fluorescence reader (FLx800TM, BioTeK Instruments Gen5TM software, USA). For the determination of fluorescence intensity, the following equation was used.

$$I = I_{det} - I_{com}$$

Here, I_{det} is the determination of fluorescence intensity and I_{com} is the fluorescence intensity of the complex.

2.4 Computational details

2.4.1 Density Functional theory

All computations were accomplished by means of Gaussian 09/DFT program package [7]. Beck's three parameter hybrid exchange functional B3 [8] along with Lee-Yang-Parr correlational functional [9], employing the 6-311++G (d,p)/SDD basis set was used for the ligands and their metal complexes analogues. These basic functionals are more accurate and reduce the computational rate and include few relativistic effects in the calculations [10-12].

We calculated the total molecular dipole moment (μ_t) and its components; total molecular Polarizability (α_t) and its components; anisotropy of Polarizability ($\Delta\alpha$); and first order static hyperpolarizability (β_t) using density functional theory based on finite field approach and following Buckingham's definitions [13], in order to understand NLO behaviour of the ligands and their metal complexes.

Molecular electronic properties such as ionization potential (I), electron affinity (A), global hardness (η), chemical potential (μ), global electrophilicity power (ω) of the compounds obtained from frontier molecular orbital energies comprising HOMO (Highest Occupied Molecular Orbital) and LUMO (Lowest Unoccupied Molecular Orbital) using the following expressions [14-17].

$$I = -E_{HOMO}; A = -E_{LUMO}; \eta = (-E_{HOMO} + E_{LUMO})/2; \mu = (E_{HOMO} + E_{LUMO})/2; \text{ and } \omega = \mu^2/2\eta$$

Where, E_{HOMO} and E_{LUMO} are HOMO and LUMO orbital energies, respectively.

To get an idea of various second order interactions between the filled orbitals of one subsystem and vacant orbitals of another subsystem, natural bond orbital (NBO) calculations were made, employing NBO 3.1 program [18], as implemented in the Gaussian 09W program package at the DFT/ B3LYP level using 6-311++G(d,p)/SDD basis set. Such calculations are needed to quantify hyper conjugation (or delocalization). This is achieved by evaluating donor-acceptor interactions using second order perturbation theory analysis of Fock matrix in NBO basis of compounds. The interactions manifest as loss of occupancy from the localized NBO of the idealized Lewis structure into an empty non-Lewis orbital. The stabilization energy associated with the

delocalization is obtained from the equation provided by Reed et al. [18], and Chocholousova et al. [19].

2.4.2 Molecular docking studies

Our aim was to explain the interactive mechanism of ligands and its complexes with the target receptor and to examine the possible binding modes with target EGFR protein receptor and selected molecular docking simulations. EGFR/HER2 plays a major role in cancer and is the main target for cancer inhibitors. Mutations lead to over expression of EGFR/HER2 and it is associated with a number of cancer diseases including squamous-cell carcinoma of the lung (80% of cases), anal cancers [20], glioblastoma (50%) and epithelial tumors of the head and neck (80-100%) [21]. The docking study was carried out on EGFR protein receptor with ligands and metal complexes. Crystallographic structure of EGFR/HER2 (PDB ID: 4hjo/3ppo) was retrieved from RSC protein data bank. EGFR/HER2 protein was cleaned by removing water molecules and ligands present in the UCSF Chimera. The 2D structures of metal complexes were drawn in Chem Draw Ultra 12.0 and 3D structures were fully optimized with small hf/3-21g* [22], basic set by using Gaussian 09.

2.4.3 Molecular docking protocol

To carry out the molecular docking study, AutoDock Tools (ADT) (<http://mgltools.scripps.edu>) version 1.5.6 and Autodock 4.2 package suite (<http://autodock.scripps.edu/resources/references>) were chosen. In the ADT process, the rigid protein receptor EGFR/HER2 ligands and their complexes were made to interact with each other. Gasteiger charges were added to each atom of protein structure and non-polar hydrogen atoms were merged. For further studies in ADT, PDB structures were converted to PDBQT format while the energy calculations were done using genetic algorithms. Nonpolar hydrogen atoms, Gasteiger partial charges, rotatable bonds and grid box with dimensions $60 \times 60 \times 60 \text{ \AA}^3$ created around the EGFR/HER2 protein receptor were assigned with the aid of Autodock tools 1.5.6 and spacing of (Angstrom): 0.3750 \AA . The population size and the maximum number of evaluations were 150 and 25,00,000, respectively. Discovery studio 4.1.0 was used to explore the results obtained. The complete process describes the detailed docking studies of EGFR/HER2 inhibitors including binding energies of receptor compound complexes.

Table 2.1 Synthetic details and physical characteristics of the metal complexes

| S.No. | Metal salt | Wt. of the metal salt taken (g) | Ligand | Wt. of the ligand taken (g) | Refluxing time (min.) | Colour of the complex |
|-------|---|---------------------------------|-----------------|-----------------------------|-----------------------|-----------------------|
| (1) | (2) | (3) | (4) | (5) | (6) | (7) |
| 1 | CoCl ₂ .6H ₂ O | 0.238 | AN _A | 0.244 | 180 | Brown |
| 2 | NiCl ₂ .6H ₂ O | 0.237 | " | 0.244 | 180 | Reddish brown |
| 3 | CuCl ₂ | 0.134 | " | 0.244 | 120 | Brownish-black |
| 4 | ZnCl ₂ .4H ₂ O | 0.208 | " | 0.244 | 180 | Yellow |

2.5 Description of the Instruments used and the experimental details

The instruments used in the present investigations and the experimental details are presented below

2.5.1 Conductance measurements

The use of conductivity measurements in organic solvents for the characterization of metal complexes has been known for a long time. Several solvents such as acetone, nitromethane, nitrobenzene, methanol, ethanol, acetonitrile, dimethylformamide, dimethylsulphoxide, pyridine, etc. have been tried for the purpose and a solvent with high dielectric constant and low viscosity is usually preferred. The use of a particular solvent for conductivity measurements of a compound is also governed by the solubility of it in that solvent.

The conductance measurements of metal complexes are usually made at a concentration 10^{-3} M. The molar conductance (Λ_M) is obtained by the following equation

$$\text{Molar conductance} = \frac{\text{specific conductance} \times \text{cell constant}}{\text{concentration}} \times 1000$$

Literature survey indicates that dimethylformamide and nitrobenzene are the most extensively used non-aqueous solvents for conductance measurements. Sears and co-workers [23] measured the conductance of a number of 1:1 electrolytes in dimethylformamide at 25 °C over a range of concentrations. It is observed that molar conductance values in a particular solvent are different for different electrolyte types and for the same electrolyte type again they are different in different solvents. The expected Λ_M ranges ($\text{ohm}^{-1} \cdot \text{cm}^2 \cdot \text{mol}^{-1}$) for metal complexes of different electrolyte types at 10^{-3} M in some common organic solvents were summarized by Geary [24] and are as follows.

| Solvent | Electrolyte type | | | |
|--------------|------------------|---------|---------|---------|
| | 1:1 | 1:2 | 1:3 | 1:4 |
| Nitromethane | 75-95 | 150-180 | 220-260 | 290-330 |
| Nitrobenzene | 20-30 | 50-60 | 70-82 | 90-100 |
| Acetone | 100-140 | 160-200 | 270 | 360 |
| Acetonitrile | 120-160 | 220-300 | 340-420 | 500 |
| DMF | 65-90 | 130-170 | 200-240 | 300 |
| Methanol | 80-115 | 160-220 | 290-350 | 450 |
| Ethanol | 35-45 | 70-90 | 120 | 160 |

A Systronic model-304 cell type CD-10 digital conductivity meter, with a cell calibrated with 0.1 M KCl solution was used.

2.5.2 Magnetic susceptibility measurements

The measurement of magnetic susceptibility constitutes one of the most important methods that enable the chemist to procure information on the structure and bonding in transition metal complexes. Such measurements have indeed contributed much to the characterization of complex compounds with respect to reactivity and the type of metal-ligand bond.

There are two types of magnetism which are of considerable interest in the study of metal complexes: paramagnetism and diamagnetism. Paramagnetism is shown by substances containing one or more unpaired electrons. When a paramagnetic substance is placed in a magnetic field, the atomic or molecular permanent magnets align themselves in the same direction as the applied field and are thus attracted to it. Diamagnetism arises as a result of the interaction of the applied field with closed shell electrons, inducing a magnetic moment which must, therefore, oppose the applied field. The diamagnetic effect is usually several orders of magnitude weaker than the paramagnetic effect and its importance in inorganic systems is primarily a correction term for precise work.

Chemically useful information is obtained by proper interpretation of magnetic moments. The moments are calculated by measuring magnetic susceptibility and these two are related by the following equation:

$$\Psi_m (\text{corr}) = N\mu^2/3KT$$

Where Ψ_m (corr) = Corrected molar susceptibility

μ = Magnetic moment

N = Avogadro number

K = Boltzman constant

and T = Absolute temperature at which the measurement is made.

On evaluating the constants, the magnetic moment (effective) can be calculated as,

$$\mu_{\text{eff}} = 2.84 \sqrt{\Psi_m \text{ (corr)} \cdot T}$$

The magnetic properties of the transition metal complexes can be explained very satisfactorily by ligand field theory. In this theory, the inner orbitals of interest in complex study are partially filled d orbitals. The d orbitals being degenerate in the free ion will be split up in a complex into different energy levels due to the ligand field. The number of unpaired electrons present in the central ion of the complex can be arrived at following an understanding of the nature and extent of splitting along with the possible application of Hund's rule.

The magnetic moment of a transition metal complex is a combination of spin and orbital moments. In many complexes, the ligand field almost completely quenches the orbital contribution and the magnetic moment can be calculated by the following spin-only formula:

$$\mu = \sqrt{\Psi_m \text{ (corr)} \cdot T}$$

Where S is the total spin of the complex, however, in some others, the experimental μ values differ significantly from the simple spin-only values. The deviations are generally due to incomplete quenching of the orbital magnetic moment by the ligand field. In other words, there would be allowances to magnetic moment of a system in terms of orbital motion and spin-orbital coupling.

The magnetic susceptibilities of the complexes were measured using Sherwood scientific auto magnetic susceptibility balance. Gouy balance was used to measure the magnetic susceptibilities of the complexes in solid state at room temperature using $\text{Hg}[\text{Co}(\text{SCN})_4]$ as calibrant. Diamagnetic corrections were calculated from Pascal's constants.

2.5.3 Thermal studies

Thermo gravimetric analysis which involves the measurement of changes in weight as a function of temperature provides information relating to certain physical and chemical phenomena such as vaporization, decomposition, etc. The technique enjoys wide applicability in different branches of chemistry. Studies of inorganic compounds and complexes by this technique are concerned with their stability, decomposition and structure. The data obtained are often useful to determine, along with other things, the stability of compounds at higher temperatures and to investigate further the dependence of thermal stability on the structure of compounds.

The importance of the investigation of thermal stability of complexes has been emphasized by Bowman and Rogers [25]. Several metal complexes with ligands of different types have been studied by this technique [26]. Bottei and Greene [27] employed the decomposition temperatures in the case of metal chelates of chloroanilic acid, rhodizonic acid and tetrahydroxyquinoline as a measure of their thermal stability. Sheshagiri and Rao [28] have worked out the relation between the solution stability and thermal stability in the case of some metal complexes of resacetophenoneoxime and found that both the stabilities might have been much studied [29] for their thermal behaviour.

The thermal stability of complexes has been related to several rezone such as π -electron delocalization, size of the molecule, number and nature of the rings formed, electron density at the reactive centre, etc. [26,29]. Despite good amount of work, considerable difficulty still exists in assigning definite reasons for the increase or decrease in thermal stability of metal complexes with different ligands.

The thermal gravimetric analysis of the metal complexes was performed on NETZSCH STA-2500 Regulus thermo analyzer under nitrogen atmosphere (RT-800 °C) at the heating rate of 10°C/ min.

2.5.4 Infrared spectra

Infrared spectroscopy is eminently suited for different types of structural investigations because of the ideal wavelength region it covers in the electromagnetic spectrum. This gives considerable information not only to the structural features but also provides finger-prints of molecules. Various groups present in the molecule give rise to characteristic frequencies for the stretching and bending of the bonds. As these

frequencies are altered only slightly by the presence of other groups, they can be used for diagnostic purpose.

Studies on the effect of coordination on the infrared spectra of metal complexes yield valuable information about the bonding present in complexes. Coordination usually results in (a) the appearance of the new bands and splitting of the degenerate modes due to lowering of symmetry and (b) change in the intensity and the frequency of bands. A study of the frequency shifts of ligand with metal together with the presence or absence of certain bands has been made to deduce structural information.

The FT-IR spectra of the ligands and their metal complexes were recorded, in the spectral range of 4000-400cm⁻¹, using Perkin-Elmer 100S spectrophotometer equipped with liquid nitrogen-cooled deuterated triglycine sulphate (DTGS) detector, by diluting the samples in KBr pellet.

2.5.5 Electronic spectra

The study of electron absorption spectra of transition metal complexes has constituted one of the major efforts by both experimentalists and theoreticians to better characterize and understand the nature of the electronic structure and bonding in these compounds [30]. The particular spectrum exhibited by any compound is dependent upon the energy of the d orbitals, their degeneracy and the number of electrons distributed in them; these features, in turn, are controlled by the oxidation state of the metal, the number and the nature of ligands and geometry of the complex.

Four types of electronic transitions may be observed with transition metal complexes:

1. Transition may occur between the split d levels of the central atom, giving rise to d-d or ligand field spectra. The spectral region where these bands occur spans the near infrared, visible and ultraviolet.
2. Transitions may occur from molecular orbitals located primarily on the ligands to non-bonding or anti bonding molecular orbitals located primarily in the central metal atom. Such transitions are called ligand-to-metal charge transfer transitions.
3. metal-to-ligand charge transfer transitions due to electrons being excited from non-bonding or anti bonding orbitals located primarily on the central metal atom to antibonding orbitals located primarily on the ligands.

4. Intra ligand transitions, which involve the transfer of electrons from one ligand orbital to another ligand orbital.

Bands due to charge transfer and intra ligand transitions usually occur in ultraviolet region.

The probabilities or intensities of these transitions are predicted from certain quantum mechanical selection rules called spin selection and Laporte selection rules. The spin selection rule is not completely valid in the presence of spin-orbit coupling. Therefore, spin-forbidden bands do appear in the spectra of many transition metal complexes, but they are generally weaker in magnitude than spin-allowed bands. Similarly, the d-d transitions are forbidden by Laporte selection rules and even if they occur, they do with low intensity. However, there are various factors which are responsible for the breakdown of these selection rules. The most general interpretation of the spectra of transition metal complexes is obtained from the Orgel and Tanabe-Sugano energy level diagrams. Although a detailed analysis of absorption spectra of complexes is difficult and not completely possible, several attempts have been made to relate the absorption spectra to the stereochemistry, magnetic behaviour and stability of the complexes.

The UV-Visible spectra of the ligands and their metal complexes were measured on Perkin-Elmer UV-Visible Lambda-25 double beam spectrophotometer, in the range 200-400 nm, in a solution of DMF using 1cm quartz cell.

2.5.6 ^1H NMR and ^{13}C NMR spectra

^1H and ^{13}C NMR spectra of the ligands and their complexes were recorded using Bruker Avance HD 400 MHz and 100 MHz NMR instrument, respectively. Solvents used were deuterated dimethylsulfoxide $\text{DMSO-}d_6$ or CDCl_3 . Tetramethylsilane (TMS) was the internal standard in the measurement of NMR spectra. NMR spectra were recorded at room temperature.

2.5.7 ESR spectra

Electronic spin resonance, a branch of absorption spectroscopy, is the study of interaction between electronic magnetic moments arising from system containing one or more unpaired electrons and an applied magnetic field [31].

ESR studies on Cu(II) complexes are interesting owing to the fact that their ground states are orbitally degenerate in regular geometries and non-degenerate in distorted cases. Since an orbitally degenerate conformation is susceptible to Jahn-Teller distortion, the nature of which is strongly dependant on the way in which the complex tends to be bonded, the study of such confirmation can give insight into the nature of bonds. The majority of Cu(II) complexes give rise to orbitally non-degenerate $d_{x^2-y^2}$ ground state, a substantial number have d_z^2 ground state and some have d_{xy} ground state.

The Cu(II) ion with a d^9 configuration has an effective spin of $S = 1/2$ and is associated with spin angular momentum, $m_s = \pm 1/2$ leading to a doubly degenerate spin state in the absence of a magnetic field. When a magnetic field is applied, the spin degeneracy is resolved. The low energy state has spin magnetic moment aligned with the field and corresponds to the quantum number $m_s = -1/2$ which the high energy state $m_s = +1/2$ has its moment opposed to the field. The energy difference between the two states is given by

$$E = h\vartheta = g\beta H$$

Where, h = Planck's constant

ϑ = Frequency of radiation

g = Lande splitting factor

β = Bohr magneton

H = Field strength.

g is not constant but a tensor quantity. For a free electron, the g value is 2.0023. In metal ions the g value is different from the free electron value. In general, the magnitude of g depends upon the orientation of the unpaired electron containing molecule with respect to the magnetic field. If the paramagnetic species is located in a perfectly cubic crystal site (an octahedral or tetrahedral site), the g value is independent of the orientation of the crystal is said to be isotropic. In a crystal site of lower symmetry, the value depends on the orientation of the crystal and is said to be anisotropic.

Basically, the interpretation of the ESR spectrum of an isolated transition metal ion yields values for two kinds of parameter (1) the spectroscopic splitting factor (g values) which describe the frequencies or energies required to bring about transitions between the different electron spin states and (2) the hyperfine coupling constants which

give a measure of electron spin-nuclear spin interactions. These parameters are affected by the presence of ligands around the central metal ion.

The X-band ESR spectra of the Cu(II) complexes were performed in JOEL X-Band Electron Spin Resonance spectrometer working at room temperature.

2.5.8 Single crystal X-ray diffraction (XRD) measurements

XRD data for the ligands and their metal complexes were collected at 100 K on a Bruker D8 QUEST instrument with an $I\mu S$ Mo micro source ($\lambda = 0.7107\text{\AA}$) and a PHOTON-100 detector. The data collection was made in the range $2.54^\circ \leq 2\theta \leq 61.18^\circ$ (θ is the angle of diffraction), for the index ranges $-8 \leq h \leq 8$; $-10 \leq k \leq 10$; $-17 \leq l \leq 17$. Total number of reflections collected was 13043, with 3259 independent reflections ($R_{\text{int}} = 0.0231$, $R_{\text{sigma}} = 0.0245$). The raw data frames were reduced and corrected for absorption effects using Bruker Apex 3 software suite programs [32]. The structure was solved using intrinsic phasing method [33]. It was further refined with SHELXL [33] program and expanded using Fourier techniques. Anisotropic displacement parameters were included for all non-hydrogen atoms. H atoms bonded to N atoms were located in difference Fourier maps, their positions and isotropic displacement parameters were refined. All H atoms bonded to C atoms were positioned geometrically and treated as riding on their parent C atoms.

2.5.9 Elemental analysis

The analytical data of the ligands and their metal complexes were performed using a Vario EL-III CHNS analyzer.

2.5.10 Melting point

The melting points of the synthesized ligands and their complexes were determined with Stuart SMP 30 melting point apparatus and were uncorrected.

2.5.11 Cancer cell lines and antimicrobial strains

Human breast carcinoma cell line (MCF-7), human colon adenocarcinoma cell line (COLO-205), human alveolar carcinoma cell line (A549), human neuroblastoma cell line (IMR-32) and murine macrophage cell line (Raw 264.7) were obtained. All the cell lines were obtained with job number 1620 from NCCS (National Centre for Cell Science), Pune, India. Cell lines were maintained at 37°C in a humidified 5% CO_2 incubator (Thermo scientific) using suitable media prescribed in NCCS Protocol. The

gram-positive bacterial strains *Bacillus subtilis* (MTCC 96), *Staphylococcus aureus* (MTCC 121) and *Staphylococcus epidermidis* (MTCC 2639) and gram negative bacterial strains *Klebsiella pneumoniae* (MTCC 109), *Escherichia coli* (MTCC 40), and *Pseudomonas aeruginosa* (MTCC 2453). Standard pathogenic microbial cultures were procured from the Microbial Type Culture Collection and Gene Bank (MTCC), Chandigarh, India, which was recognized by the World Intellectual Property Organization (WIPO).

CHAPTER-III

Co(II), Ni(II), Cu(II), Zn(II), Cd(II) and Pd(II) metal complexes of 2-aminonicotinaldehyde: Synthesis, characterization, density functional theory, biological evaluation and catalytic applications

Pyridine and its derivatives are among the extensively used substructures for food flavorings, medicines, dyes, rubber chemicals, adhesives and agrochemicals [1]. Like pyridine heterocyclic ring, the combinative chemistry tries to produce a group of compounds, which exhibits drug activity [2,3]. Pyridyl aldehydes closely resemble aryl aldehydes largely because a carbonyl group cannot interact mesomerically with the nitrogen atom in the pyridine ring. The exploration of these compounds is of paramount importance as they are extensively employed as intermediates for the pharmaceutical, agro-industry and pharmaceutical ingredient. In recent years, the coordinate chemistry of Schiff bases derived from 2-pyridine-carboxaldehyde has encountered much awareness and since of it possesses both nucleophilicity and electrophilicity [4,5]. Due to a wide range of application in agro-chemistry and pharmacology, many spectroscopists retain the attention on vibrational spectra of substituted pyridines. Pyridine heterocycles are a periodic element in varies large molecules with interesting catalytic, electrochemical and photophysical applications [6-13]. They also perform anesthetic property and hence they are used in the development of drugs for certain brain diseases and for prevention of diabetic neuropathy [14,15].

In view of the aforementioned applications, we selected ANA as the ligand. Theoretically, there are three plausible metal binding sites in ANA. Pyridine N being the most probable electron donor site, others include amine N and aldehyde O. The option of having more than one potential metal binding site makes the investigation of the coordination chemistry of ANA is very challenging. A detailed structural study was done with spectroscopic tools like X-rays, ^1H NMR, ^{13}C NMR, FT-IR, UV-Visible, spectral techniques supported by Density Functional Theory (DFT) calculations and molecular docking, along with the evaluation of NLO behaviour to understand metal binding affinity of ANA. In addition, the compounds had been evaluated for *in vitro* antimicrobial, antioxidant, anti-inflammatory and anticancer activities, a comprehensive discussion being featured in the sections that follow.

3.1 Results and discussion

All the complexes are stable at room temperature and are non-hygroscopic. Analytical data showed that metal complexes have 1:2:2 (metal:ANA:chloride) stoichiometry as shown in Table 3.1. The ligand ANA is freely soluble in methanol and ethanol while the complexes are soluble in DMF and DMSO.

Table 3.1 Analytical and molar conductivity data of the ligand and its complexes

| Compound | Elemental analyses: Found (Calculated) | | | |
|---|---|------------------|-----------------|------------------|
| | C | N | H | M |
| [Co(ANA) ₂ Cl ₂] | 38.43 (38.49) | 14.92 (14.97) | 3.17 (3.20) | 15.70 (15.75) |
| [Ni(ANA) ₂ Cl ₂] | 38.50 (38.52) | 14.96 (14.98) | 3.20 (3.21) | 15.62 (15.69) |
| [Cu(ANA) ₂ Cl ₂] | 37.99 (38.02) | 14.75 (14.78) | 3.12 (3.17) | 16.75 (10.77) |
| [Zn(ANA) ₂ Cl ₂] | 37.80 (37.85) | 14.69 (14.72) | 3.15 (3.17) | 17.00 (17.18) |

| [Pd(ANA) ₂ Cl ₂] | 34.12 (34.15) | 13.20 (13.28) | 2.80 (2.84) | 22.50 (22.54) |
| ANA | 58.80 (58.95) | 22.87 (22.93) | 48.80 (4.91) | - - |

3.1.1 Spectroscopy

The IR spectral and molar conductivity data of ANA and its metal complexes are given in Table 3.2. $\nu_{\text{N-H}}$ of NH₂ of ANA occurs at 3414 cm⁻¹, the peak at 1667 cm⁻¹ is assigned to $\nu_{\text{C=O}}$ of CHO group and the peak at 1590 cm⁻¹ is assigned to stretching frequency of the $\nu_{\text{C=N}}$ of the pyridine ring. The IR spectra of the complexes are similar to ANA with minor shifts in the position of peaks. In all the spectra of complexes, $\nu_{\text{C=N}}$ (py) peak shifted significantly to lower wave number by 30-50 cm⁻¹[16,17] implying that the pyridine nitrogen of ANA is coordinated to metal centre. In the far-IR region, the new peaks observed at 472-421 cm⁻¹ and 362-290 cm⁻¹ were assigned to $\nu_{\text{M-N}}$ and $\nu_{\text{M-Cl}}$, respectively [18,19]. The molar conductance values of the complexes (10-16 Ω⁻¹cm²mol⁻¹) are too low to account for any dissociation of the complexes in DMF, indicating that

they are non-electrolytes [20]. This implies that chloride anions associated with these complexes are present inside the coordination sphere.

The electronic absorption studies and magnetic measurements provide quick and reliable information about the geometry of metal complexes. These data can serve as an effective tool to differentiate the geometries of the metal complexes. The electronic spectral bands and magnetic moment values of the metal complexes are listed in Table 3.3. The UV-Visible spectrum of ANA showed two bands at 38461 and 28653 cm^{-1} corresponding to $\pi \rightarrow \pi^*$ and $n \rightarrow \pi^*$ transitions, respectively. The UV-Visible spectrum of Co(II) complex usually showed three bands in the region of 3000-5000, 6000-10000 and 15000-21000 cm^{-1} , which may be assigned to $^4\text{A}_2(\text{F}) \rightarrow ^4\text{T}_2(\text{F})$, $^4\text{A}_2(\text{F}) \rightarrow ^4\text{T}_1(\text{F})$ and $^4\text{A}_2(\text{F}) \rightarrow ^4\text{T}_1(\text{P})$ transitions, respectively. However, in the present case, Co(II) complex showed two bands at 9000 and 20400 cm^{-1} characteristic of tetrahedral geometry [21]. Ni(II) complex was found to be paramagnetic and its absorption spectrum showed two bands at 9500 and 19157 cm^{-1} , which could be assigned to $^3\text{T}_1(\text{F}) \rightarrow ^3\text{A}_2(\text{F})$ and $^3\text{T}_1(\text{F}) \rightarrow ^3\text{T}_1(\text{P})$ transitions, respectively are characteristic of tetrahedral geometry [22]. The Cu(II) complex exhibited a band at 24096 cm^{-1} and a shoulder at 12195 cm^{-1} , which may be due to $^2\text{B}_{1g} \rightarrow ^2\text{B}_{2g}$ and $^2\text{B}_{1g} \rightarrow ^2\text{E}_g$ transitions, respectively which is characteristic of square-planar geometry [23]. Pd(II) complex exhibited two bands at 22540 and 31750 cm^{-1} , which may be assigned to $^1\text{A}_{1g} \rightarrow ^1\text{E}_g$ and charge transfer transitions which are characteristic of square-planar geometry [24]. No d-d transitions are expected for Zn(II) and Cd(II) complexes, because of d^{10} electronic configuration. Based on single crystal XRD, IR, UV-Visible and other analytical data, tetrahedral geometry has been proposed [25].

Square-planar Cu(II) complexes showed magnetic moment values in the range of 1.8-2.1 B.M. These values are somewhat greater than the spin-only value of 1.73 B.M. and this is due to the spin-orbit coupling followed by lowering of symmetry [26]. In the present study, magnetic moment value of Cu(II) complex is 2.01 B.M. which supports a square-planar geometry around the metal ion [27]. The magnetic moment of Co(II) complex is 4.71 B.M. which suggests high spin tetrahedral geometry [28]. Ni(II) complex is also paramagnetic and the magnetic moment is found to be 2.91 B.M. in good agreement with tetrahedral geometry [29]. Pd(II), Zn(II) and Cd(II) complexes are diamagnetic in nature and based on this, square- planar and tetrahedral geometry have been proposed [30]. Electron Spin Resonance spectrum of Cu(II) complex was recorded

in solid state at room temperature. The solid state spectrum of Cu(II) complex is shown in Fig. 3.1. The solid state spectrum of Cu(II) complex is anisotropic and showed two peaks, one corresponding to \mathbf{g}_{\parallel} and the other to \mathbf{g}_{\perp} . The observed \mathbf{g}_{\parallel} and \mathbf{g}_{\perp} values are 2.14, 2.08, respectively. The \mathbf{g}_{\parallel} value of the complex is less than 2.3 indicating covalent character of the metal-ligand bond [31]. Further, the, $\mathbf{g}_{\parallel} > \mathbf{g}_{\perp} > 2.0023$, pointing out that the metal ion contains unpaired electron predominantly lies in $d_{x^2-y^2}$ orbital, with square-planar geometry around Cu(II) ion [32]. The geometric parameter G is calculated using the equation

$$G = \frac{g_{\parallel} - 2.0023}{g_{\perp} - 2.0023}$$

According to Hathaway and Billing [33], if the value of G is greater than 4, it indicates that the exchange interaction between Cu(II) centers in the solid state is negligible. Whereas, its value is less than 4 considerable exchange interactions exist in the solid complex. The value for the exchange interaction parameter G for the present Cu(II) complex is 1.77 which is less than 4 indicating there is a spin exchange interacting between Cu(II) ions in the solid state. The thermograms of complexes were heated from 25-800 °C under nitrogen atmosphere. The Co(II) complex is thermally stable up to 225 °C and above this temperature up to 585 °C, it records a weight loss in a continuous manner that corresponds to two molecules of ANA. The resulting moiety is stable for up to 680 °C above which it shows a weight loss, the final product corresponding to CoO as residue. The Ni(II) complex is stable up to 340 °C above which it loses weight continuously up to 550 °C to give NiO as the final product. In Cu(II) complex, a weight loss has been observed in the range of 180-425 °C that amounts to one molecule of ANA. The residue that results appears to be stable up to 480 °C. Thereafter, the thermogram records another weight loss in the range 480-750 °C that corresponds to the loss of remaining ligand moiety. The horizontal line observed over 750 °C corresponds to CuO. Zn(II) complex decomposed gradually leading to the loss of organic ligands from 230-345 °C, continuously to retain ZnO as residue. In case of Cd(II) complex, decomposition started from 218-360 °C for the loss of organic moieties to retain CdO as residue, whereas in case of Pd(II), the complex shows a horizontal line up to 300 °C and above which it starts losing weight in a continuous manner up to 750 °C, which corresponds to PdO. The ¹H NMR spectrum of ligand showed the signals at 9.84 (s, 1H, CHO), 8.24 (d, $J = 8.0$ Hz, 1H), 8.00 (d, $J = 8.0$ Hz, 1H), 7.55 (s, 2H, -NH₂), 6.72-6.75 (m, 1H). ¹³C NMR spectrum

of ANA exhibits signals from 112.69 to 194.12 ppm. The signal at 194.12 is assigned to aldehyde carbon while the peaks at 155.36 and 112.69 ppm are due to quaternary carbons and the peaks at 113.44, 145.02 and 158.70 ppm are for the remaining carbons. These peaks in the spectra of complexes which appeared with positive coordination induced shifts indicate pyridine N of ANA was involved in bonding with metal ions. The ^1H and ^{13}C NMR spectra of ANA and its metal complexes are represented in Fig. 3.2.

Table 3.2 IR (cm^{-1}) and molar conductivity data of the compounds

| Compound | $\nu_{\text{N-H}}$ | $\nu_{\text{C=O}}$ | $\nu_{\text{C=N(py)}}$ | $\nu_{\text{M-N}}$ | $\nu_{\text{M-Cl}}$ | Molar cond. ($\Omega^{-1}\text{cm}^2\text{mol}^{-1}$) |

3.1.2 Crystal structure of ANA and its Zn(II) complex

3.1.2.1 ANA

The ligand ANA crystallized in the monoclinic system with a space group $P2_1/c$ with $Z = 8$. The crystallographic parameters are listed in Table 3.4 and the H-bonding data is listed in Table 3.5. In the crystal structure, an asymmetric unit consists of two molecules of ANA, labeled separately as A and B, which has intramolecular classical N-H.....O

H-bonding occurs between one of the hydrogens of the amine group and the oxygen atom of aldehyde group forming a six membered ring Fig. 3.3. It is intriguing to note that intermolecular H-bonding between N-H.....N of the molecules gives rise to two types of primary molecular pattern N4-H4b.....N3 interactions in the dimeric unit (BB*) at the inversion centre of molecules B and N2-H2b.....N1 interaction monomer unit of the molecules A, leading to herring bone stacking pattern of molecules along b axis Fig. 3.4-a,b. Further, the non-classical weak hydrogen bond interactions between pyridine ring C-H.....N units (BB*/B*B), give rise to a different herring bone stacking pattern of dimeric units Fig. 3.4-c. In addition, the aldehydic hydrogen H12, the pyridine ring hydrogen H9 of dimers BB* and H4 of molecules A involved in intermolecular non-classical C-H.....O H-bonding with oxygen atom as trifurcated acceptor O1 [34], of molecule A is shown in Fig. 3.5. The pyridine ring hydrogen H3 of molecule A is also involved in intermolecular weak H-bonding with aldehydic oxygen atom O2 of molecule B, extending the stacking of molecules on 2D structure Fig. 3.6. Offset π - π stacking interactions established between the aromatic pyridine rings of dimeric units BB* (distance between centroids 3.955 \AA) reinforce crystal structure cohesion in molecular packing within the crystal lattice [35,36]. In a nutshell, the 3D supramolecular stacking pattern of ANA consists of classical and non-classical H-bonding network for its 3D-architecture as depicted in Fig. 3.7.

3.1.2.2 $[\text{Zn}(\text{ANA})_2\text{Cl}_2]$ complex

$\text{Zn}(\text{II})$ complex crystallized in the triclinic system with $P-1$ space group with $Z=2$. The crystallographic data are listed in Table 3.4, and details of H-bonding data are listed in Table 3.5. The coordination environment around the zinc atom is a distorted tetrahedral with two sites occupied by the pyridine nitrogen atom of ANA, labeled separately as A and B, while the remaining two sites are occupied by chloride ions Cl1 , Cl2 . The ORTEP diagram of $\text{Zn}(\text{II})$ complex is shown in Fig. 3.8, while the selected interatomic distances and bond angles are listed in Table 3.6. From the data, it is observed that both classical and non-classical H-bonding interactions are also present in $\text{Zn}(\text{II})$ complex. The intramolecular H-bonding $\text{N-H} \dots \text{O}$ as observed in the crystal structure of ANA is retained in the structure of the complex. In addition, non-classical intramolecular hydrogen bonds as $\text{N-H} \dots \text{Cl}$ occurring as $\text{N4-H4b} \cdots \text{Cl2}$ and $\text{N2-H2} \cdots \text{Cl1}$ are found in the complex molecule as shown in Fig. 3.8. As observed in the free ligand, $\text{Zn}(\text{II})$ complex shows the presence of non-classical intermolecular hydrogen bonds. One of the chloride ligands is involved in the intermolecular non-classical pyridine ring $\text{C10-H10} \dots \text{Cl2}$ hydrogen bond interaction giving rise to a 1-D array of the complex which is shown in Fig. 3.9. The oxygen atom O1 of aldehyde group of ligand A in the complex molecule acts as a bifurcated acceptor for the pyridine ring hydrogens H4 and H5 , while H3 hydrogen and aldehyde hydrogen H6 of the ligand “A” in the same complex molecule take part in non-classical intermolecular weak H-bonding with bifurcated acceptor oxygen atom O2 of ligand, which runs parallel along c axis and is shown in Fig. 3.10. Thus, in a 3D crystal structure, one ANA ligand in the complex is involved in two kinds of bifurcated intermolecular weak H-bonding through the oxygen atom of the aldehydic group. The 2D network of these non-classical hydrogen bonds is depicted in Fig. 3.11. It is interesting to note that both ANA and $\text{Zn}(\text{II})$ complex invoke classical and non-classical H-bonding arrays resulting in 3D architecture for supramolecular stacking pattern of molecules Fig. 3.12.

3.2 DFT studies

3.2.1 Molecular geometry

The optimized geometric structures for the ligand and its metal complexes were performed with DFT/B3LYP employing 6-311G++(d,p)/SDD basis set resulting in minimum energy for C_1 point group symmetry for the complexes with minimum optimization. The energy of the compounds are -3136.870070 Hartree [Co(II)], -3262.65187 Hartree [Ni(II)],

-3394.802234 Hartree [Cu(II)], -3516.405300 Hartree [Zn(II)], -1922.1703745 Hartree [Cd(II)], -1882.277588 Hartree [Pd(II)] and -417.094083 Hartree [ANA], respectively, and the optimized structures are presented in Fig. 3.13. The geometrical parameters such as bond distances, bond angles and dihedral angles of ligand ANA and its metal complexes are reported in Table 3.7.

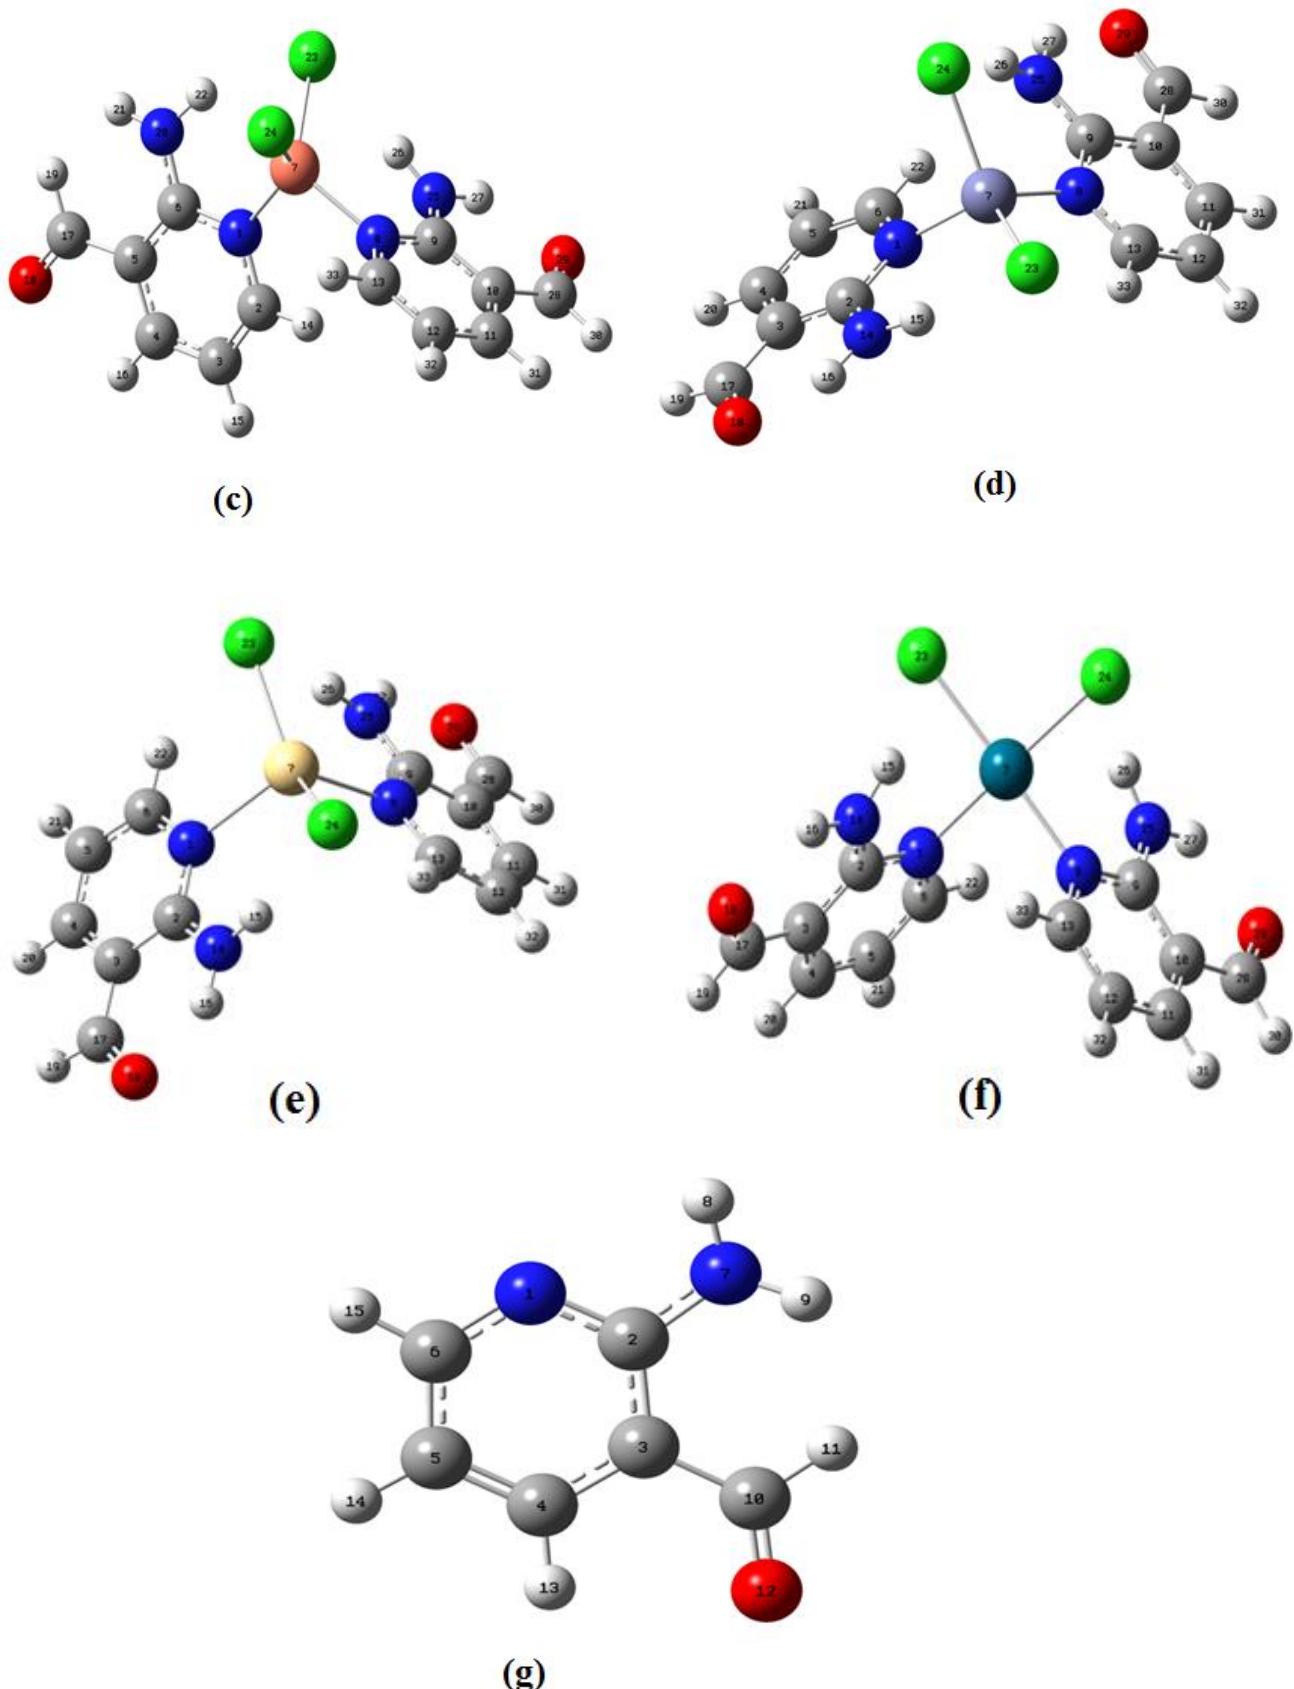

Fig. 3.13 Optimized molecular structures and numbering of atoms of (a) Co(II), (b) Ni(II), (c) Cu(II), (d) Zn(II), (e) Cd(II), (f) Pd(II) and (g) ANA.

3.2.2 NLO properties

The large values of first order hyperpolarizabilities of molecules imply that they are high potential candidates for non-linear optical (NLO) property, which finds generous applications in the fields of engineering, physics and chemistry. The hyperpolarizability, polarizability and dipole moment are characteristic properties of molecules in the presence of applied electric field [37-39]. The first order hyperpolarizability is a third rank tensor, which has 27 components, represented by a 3 x 3 x 3 matrix. These 27 components get reduced to 10 components due to Kleinman symmetry [40], which are characterized as β_{xxx} , β_{xxy} , β_{xyy} , β_{yyy} , β_{xxz} , β_{xyz} , β_{yyz} , β_{xzz} , β_{yzz} and β_{zzz} . They can be delibereate using the following equation [41]

$$\beta_i = \beta_{iii} + (1/3) \sum_{i \neq j} (\beta_{ijj} + \beta_{jji} + \beta_{iji})$$

The total static dipole moment μ_t , the anisotropy of polarizability $\Delta\alpha$, the isotropic (or average) linear polarizability α_t and the mean first order hyperpolarizability β_t , employing the x, y and z components are defined as:

$$\mu_t = (\mu_x^2 + \mu_y^2 + \mu_z^2)^{1/2}$$

$$\Delta\alpha = 2^{-1/2} [(\alpha_{xx} - \alpha_{yy})^2 + (\alpha_{yy} - \alpha_{zz})^2 + (\alpha_{zz} - \alpha_{xx})^2 + 6\alpha_{xx}^2]^{1/2}$$

$$\alpha_t = (\alpha_{xx} + \alpha_{yy} + \alpha_{zz})/3$$

$$\beta_t = (\beta_x^2 + \beta_y^2 + \beta_z^2)^{1/2}$$

Hence, the first order hyperpolarizability and its constituents; the total molecular polarizability (α_t) and its elements; the total molecular dipole moment (μ_t) and calculated to determine the NLO behaviour of the complexes and the results are reported in Table 3.8.

The direction of charge delocalization is theoretically calculated by β component. The observed first hyperpolarizability values along β_{zzz} direction indicate that the complexes are acceptable for developing the crystals along this direction in NLO applications. The calculated electronic dipole moment values were found to be 11.5846 [Co(II)], 10.0277 [(Ni(II)], 7.8673 [(Cu(II)], 10.6475 [(Zn(II)], 8.0237 [(Cd(II)] and 12.8373 [Pd(II)] Debye, respectively. The first hyperpolarizability values of the complexes are found to be 22.590×10^{-30} [Co(II)], 16.518×10^{-30} [(Ni(II)], 9.256×10^{-30} [(Cu(II)], 7.271×10^{-30} [(Zn(II)], 6.795×10^{-30} [Cd(II)] and 14.490×10^{-30} cm⁵/esu

[(Pd(II)], respectively. The large value of hyper polarizability indicates the NLO property of the system, which is interlinked with the intra-molecular charge transfer.

Table 3.8 Values of dipole moment μ_t (in Debye) and first order hyperpolarizability β_t (in 10^{-30} $\text{cm}^5/\text{e.s.u}$) of Co(II), Ni(II), Cu(II), Zn(II), Cd(II) and Pd(II) metal complexes

3.2.3 Frontier Molecular Orbitals

HOMO-LUMO energy gap can be used to determine the chemical reactivity of the compounds. The HOMO-LUMO energy gap can play a vital role in the determination of stability and reactivity of the molecules [42]. LUMO and HOMO are the two different important molecular orbitals. HOMO refers to ability to donate electron, while LUMO to the ability to accept an electron. Using HOMO, LUMO orbital energies, the electron affinity (A), chemical potential (μ), ionization energy (I), global electrophilicity power (ω) and global hardness (η) [43-45] were calculated.

The computed HOMO, LUMO energies and frontier energy gap at B3LYP/6-31G (d,p)/SDD, level for the complexes are shown in Fig. 3.14 and Table 3.9. From the results, we predict that chemical potential values of the compounds are negative and the frontier molecular gap is very small. Hence the complexes under investigation are most stable and polarizable.

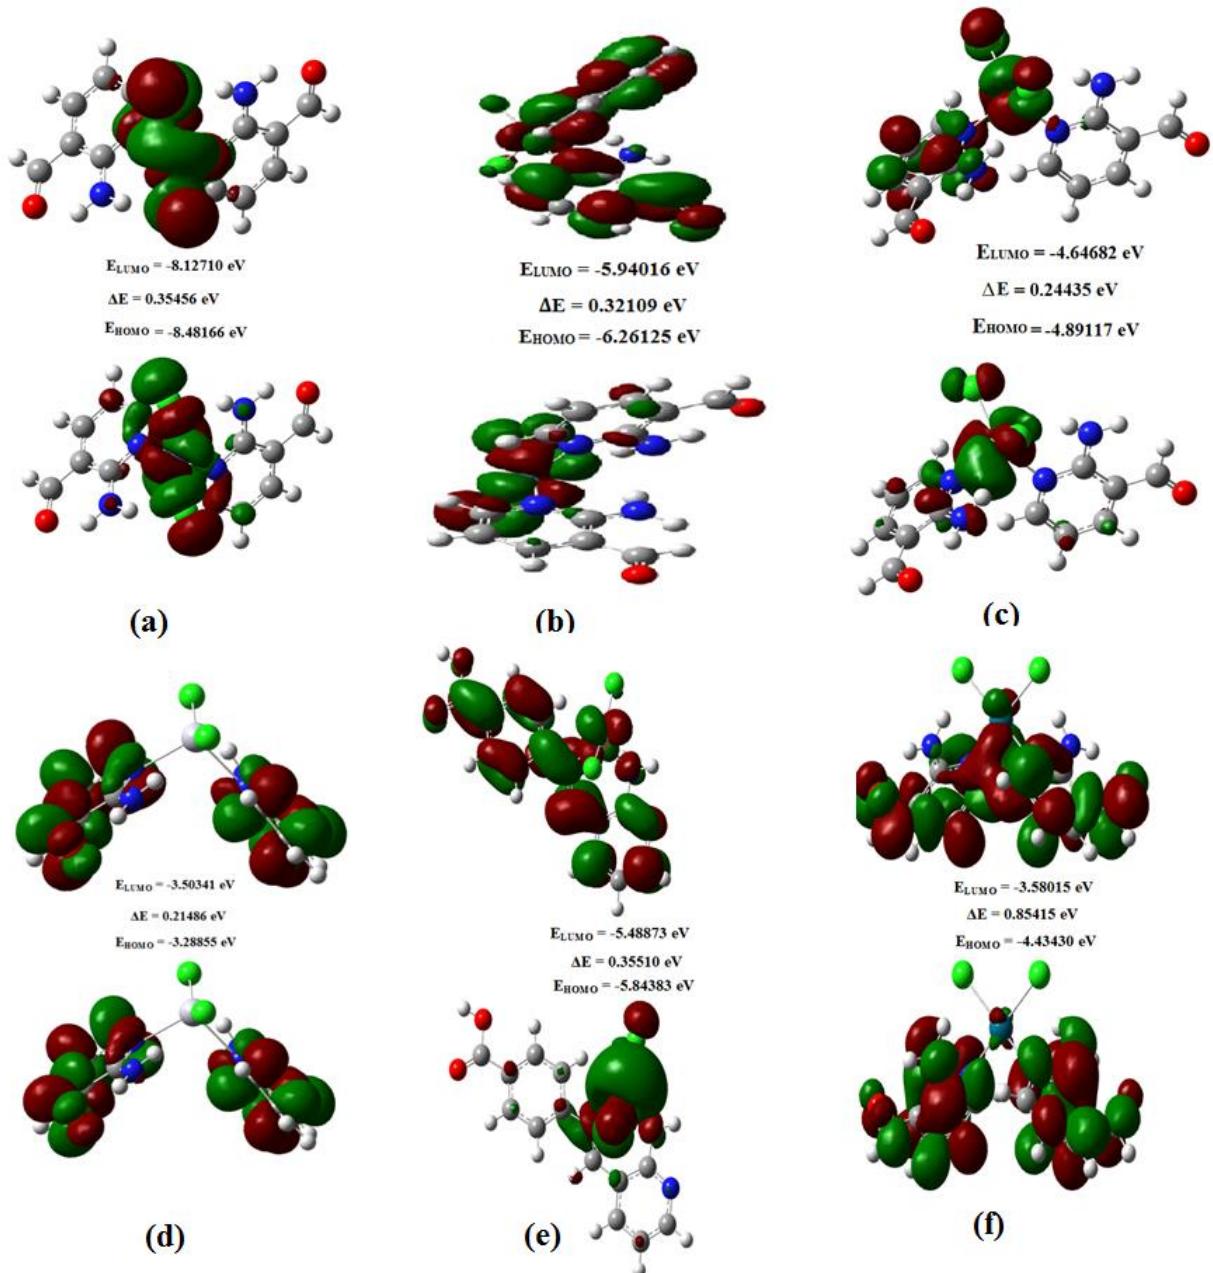

Fig. 3.14 Frontier molecular orbital energy gap of (a) Co(II), (b) Ni(II), (c) Cu(II), (d) Zn(II), (e) Cd(II) and (f) Pd(II) complexes.

Table 3.9 Frontier molecular orbital parameters of metal complexes values present (eV)

| Frontier molecular orbital parameter | Co(II) | Ni(II) | Cu(II) | Zn(II) | Cd(II) | Pd(II) |

3.3 Biological evaluation

The biological activity of a compound is attributed to the results of interlinked chemical reactions or the observed manifestation of interference with a delicately balanced system of interdependent chemical and physical process.

Metals, upon which most of the life processes depend, at times share the characteristics of a two-edged sword by being beneficial to living systems on one hand and being toxic on the other. Metals, when present in optimum quantities, serve vital functions in biological systems, but the same in excessive amounts turn toxic and even lethal. In fact, the metal ion that has gained access to the circulation in sufficient amounts and is not excreted readily is toxic to an extent depending on metal itself. These metals which cannot be metabolized persist in living body and exert their toxic effects by combining with one or more reactive groups essential for normal physiological functions.

The metal binding substances (ligands) which function by chelation, have furnished many useful drugs and other substances of value in checking the toxicity of metals. The chelating compounds called metal antagonists are designed specifically to compete with the endogenous bio-chemicals for the metals and thereby prevent or reverse toxic effects and enhance excretion of the metals.

8-hydroxyquinoline, a well known analytical reagent and a ligand is found to have antibacterial activity and it has been proposed that the antibacterial action of this compound is due to its chelating trace metal ions, which are essential for the bacterial growth and bacterial function. Detailed studies have shown that 8-hydroxyquinoline when complexed with Fe(III), in 1:1 molar ratio, is highly effective and that the ligand and Fe(III) are both inactive when separated from each other. It has been suggested that 1:3 [Fe(III): 8-hydroxyquinoline] complex alone is capable of penetrating the cell membrane. Presumably, once the 1:3 complexes are inside the cell, they break down the more effective coordinatively unsaturated and charged 1:2 and 1:1 complex which bind too strongly to the membrane. It appears that the metal which increases the liposolubility of 8-hydroxyquinoline is necessary for the entry of this ligand molecule into the cell [46,47]

Certain metal chelates are active at low concentration against a range of bacteria, fungi and viruses. Thus, the organism *Staphylococcus pyrogens*, found in wound infections, is very resistant to many standard antibiotics but it succumbs dramatically to the complexes $[\text{Fe}(\text{Me}_4\text{phen})_3]^{2+}$ and $[\text{Ru}(\text{Me}_4\text{phen})_2(\text{acac})]^+$.

Different mechanisms have been put forth to explain the phenomenon. These include, amongst others, the transfer of the metal from the complex to the affected site where it exerts its toxic effect and the ligand rendering the metal ion fat soluble, thus making it act within the cell and the metal complex inactivating a virus by occupying sites on its surface which would normally be utilized in the initiation of the infection of the host cell.

The metal-ligand interaction in a biological environment assumes importance in that the metal may considerably influence the reactivity of the ligand by:

1. Changing the electron distribution in the ligand.
2. Masking a chemically active centre of the ligand.
3. Assembling the ligand molecules into a particular stereochemical form, and
4. Providing a conducting pathway for electron addition or removal.

3.3.1 Antibacterial activity

The *in vitro* antibacterial activity of the compounds were evaluated against two gram positive (*S. aureus* and *S. epidermidis*) and three gram negative (*K. pneumoniae*, *E. coli* and *P. vulgaris*) bacterial strains, and the results are illustrated in Table 3.10. It is

evident from Table 3.10 that ligand ANA doesn't show any activity against the tested strains, while Co(II) and Cu(II) complexes exhibited potent activity against *P. vulgaris* with MIC = 5.62 and 5.24 $\mu\text{g/mL}$, respectively. Cu(II) complex showed outstanding activity than the standard drug Streptomycin against *S. epidermidis* with MIC value of 10.51 $\mu\text{g/mL}$. The Co(II) and Zn(II) complexes registered promising inhibition against *S. aureus* with MIC = 12.5 and 12.5 $\mu\text{g/mL}$, respectively. The remaining compounds showed moderate to poor activity against the strains.

Table 3.10 Antibacterial activity of the compounds [MIC ($\mu\text{g/mL}$)]

| Compound | <i>S. aureus</i> | <i>S. epidermidis</i> | <i>K. pneumoniae</i> | <i>E. coli</i> | <i>P. vulgaris</i> |
|-----------------|------------------|-----------------------|----------------------|----------------|--------------------|
| Co(II) | 12.5 | 25 | 25 | 50 | 5.62 |
| Ni(II) | 50 | 100 | >100 | 50 | >100 |
| Cu(II) | 25 | 10.51 | 25 | 25 | 5.24 |
| Zn(II) | 12.5 | 25 | 25 | 25 | >100 |
| Cd(II) | 100 | 50 | >100 | >100 | 25 |
| Pd(II) | 100 | 50 | >100 | 50 | 25 |
| ANA | >100 | >100 | >100 | >100 | >100 |
| Metal chlorides | NA | NA | NA | NA | NA |
| Streptomycin | 6.25 | 12.5 | 12.5 | 6.25 | 3.25 |

NA: no activity

3.3.2 Antifungal activity

ANA and its metal complexes were investigated for their *in vitro* antifungal activity against few fungal strains such as *A. niger* and *P. notatum* and compared to standard drug Ketoconazole with minimum inhibitory concentration (MIC) values. The results of antifungal activity in MIC values of the tested compounds are presented in Table 3.11 and the results revealed that Cu(II) complex against *A. niger* and *P. notatum* and Co(II) complex against *A. niger* exhibited significant activity with MIC = 6.25, 6.25 and 6.25 $\mu\text{g/mL}$, respectively compared to reference control Ketoconazole. Zn(II) complex exhibited moderate activity against *A. niger* and *P. notatum* with MIC = 12.5 and 12.5 $\mu\text{g/mL}$. The remaining compounds showed poor activity against the tested strains.

Table 3.11 Antifungal activity of the compounds [MIC (µg/mL)]

| Compound | <i>A. niger</i> | <i>P. notatum</i> |
|-----------------|-----------------|-------------------|
| Co(II) | 6.25 | 12.5 |
| Ni(II) | 50 | 50 |
| Cu(II) | 6.25 | 6.25 |
| Zn(II) | 12.5 | 12.5 |
| Cd(II) | >100 | >100 |
| Pd(II) | 50 | 50 |
| ANA | >100 | >100 |
| Metal chlorides | NA | NA |
| Ketoconazole | 3.12 | 3.12 |

NA- no activity

3.3.3 Antioxidant activity

The IC₅₀ values of the ligand and its metal complexes are given in Table 3.12; by increasing the concentration of the compounds the scavenging activity also increases. The DPPH assay of the metal complexes was calculated as percentage inhibition (Fig. 3.15). From the results, it is shown that the scavenging effect of the free ligand (IC₅₀ = 20.60 ± 1.38 µM) is significantly lower compared to metal complexes. The antioxidant activity of Zn(II) complex showed potent activity with IC₅₀ value of 10.14 ± 2.50 µM. Ni(II) complex exerts significant activity with IC₅₀ value of 11.39 ± 1.26 µM compared to standard drug. Cu(II), Pd(II) and Cd(II) complexes showed moderate activity while the remaining compounds exhibited poor activity. According to IC₅₀ values, the scavenging activity order of the ligand and its metal complexes are Zn(II) > Ni(II) > Cu(II) > Pd(II) > Cd(II) > Co(II) > ANA.

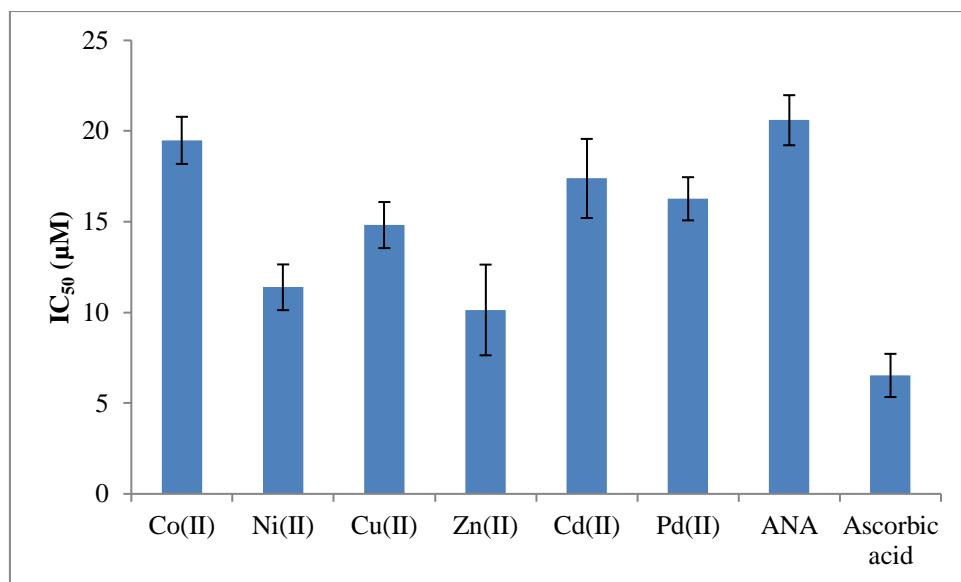

Fig. 3.15 Radical scavenging activity of ligand and metal complexes in terms of IC₅₀ value (50% inhibition)

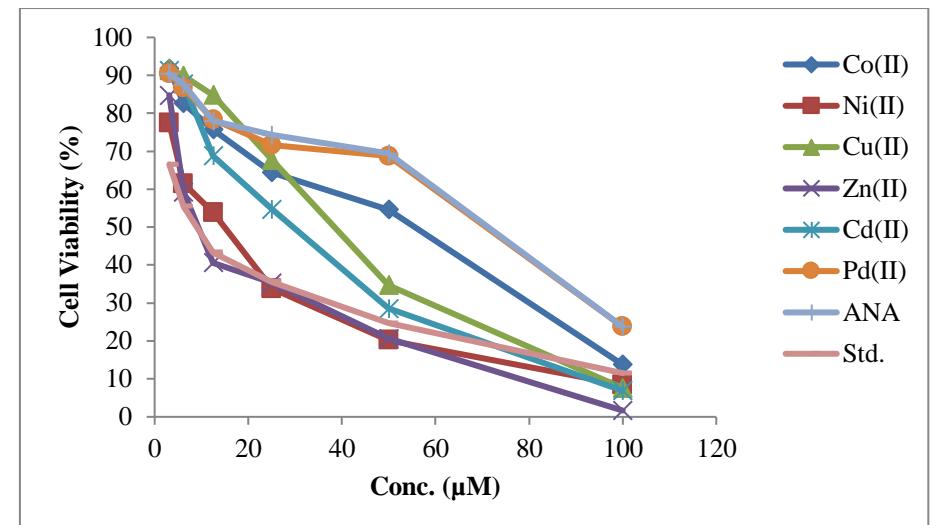

Table 3.12 IC₅₀ (μM) values of DPPH scavenging activity of ligand and its metal complexes

| Compound | IC ₅₀ |
|---------------|------------------|
| Co(II) | 19.49 ± 1.30 |
| Ni(II) | 11.39 ± 1.26 |
| Cu(II) | 14.82 ± 1.27 |
| Zn(II) | 10.14 ± 2.50 |
| Cd(II) | 17.39 ± 2.18 |
| Pd(II) | 16.27 ± 1.19 |
| ANA | 20.60 ± 1.38 |
| Ascorbic acid | 6.53 ± 1.19 |

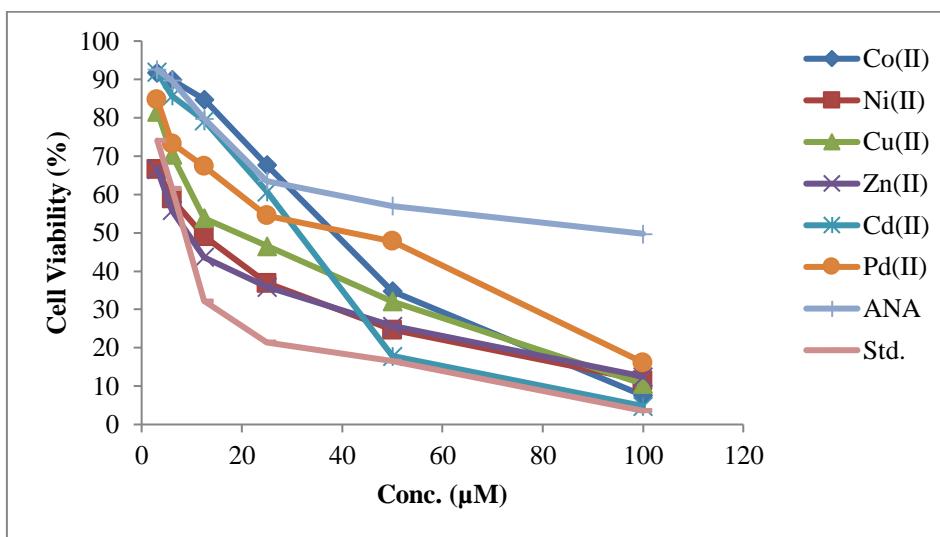

3.3.4 *In vitro* cytotoxicity investigations

A comparison of *in vitro* percentage cell viability for human carcinoma cell lines HepG-2 (hepatocellular carcinoma), IMR-32 (neuroblastoma) and Raw 264.7 (murine macrophage) at IC₅₀ values of compounds and standard drug cisplatin (CP) are listed in Table 3.13. This data is used to generate survival curves for three carcinoma cell lines under investigation by plotting percentage cell viability vs percentage concentration graphs, which appear in Fig. 3.16. The effectiveness of the new compounds against

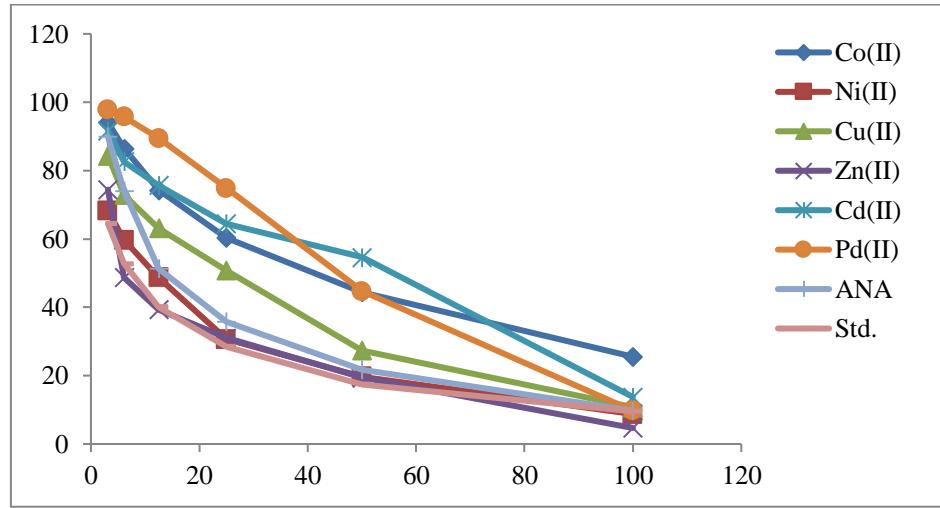

carcinoma cell lines is usually evaluated using a quantity known as the response parameter IC_{50} and comparing it with standard drug CP. IC_{50} is the concentration of the compounds or drug at which the cell viability gets inhibited by 50%. From the results, Zn(II) complex exhibited potent activity against IMR-32, HepG-2 and Raw 264.7 cell lines with IC_{50} values of 18.13 ± 0.31 , 11.63 ± 0.43 and $5.39 \pm 1.03 \mu M$, respectively. The corresponding quantity for CP is 11.67 ± 0.35 , 7.65 ± 1.03 and $3.58 \pm 1.04 \mu M$. Ni(II) complex showed good activity against IMR-32, HepG-2 with IC_{50} values of 20.51 ± 1.23 and $13.37 \pm 1.12 \mu M$. Cd(II) and Cu(II) complexes against IMR-32, Ni(II) complex against Raw 264.7 exhibited moderate activity with IC_{50} values of 41.69 ± 0.62 , 45.12 ± 1.53 and $13.26 \pm 0.19 \mu M$, respectively. The remaining compounds Co(II), Pd(II) and ANA showed poor activity with IC_{50} values ranging from 43.21 ± 0.27 to $89.54 \pm 0.15 \mu M$. The potent Zn(II) and Ni(II) complexes were also examined in normal cell line against HEK293 with IC_{50} values of 30.34 ± 1.72 and $43.98 \pm 1.58 \mu M$. The results seemed to suggest that the potent compounds are nontoxic.

3.3.5 *In vivo* anti-inflammatory activity

Carrageenan induced rat paw edema method [48] was used to asses anti-inflammatory activity in rats. The animals were divided into three groups (n = 6). Where GP-I as a control, GP-II has received a standard, Indomethacin (5 mg/kg) and GP-III was administered with test compounds (10 mg/kg) orally. After 30 min, 0.1 mL of 1 % carrageenan suspension in normal saline was injected into the sub plantar region of the left hind paw of each rat to induce edema. The activity was measured with the help of plethysmographic method at different intervals (0, 1, 2, 4, and 6 h) (Fig. 3.17), the results of which are listed in Table 3.14. Compared to all complexes, Cu(II) and Zn(II) complexes have shown better activity at different time intervals 1 h, 2 h and 6 h.

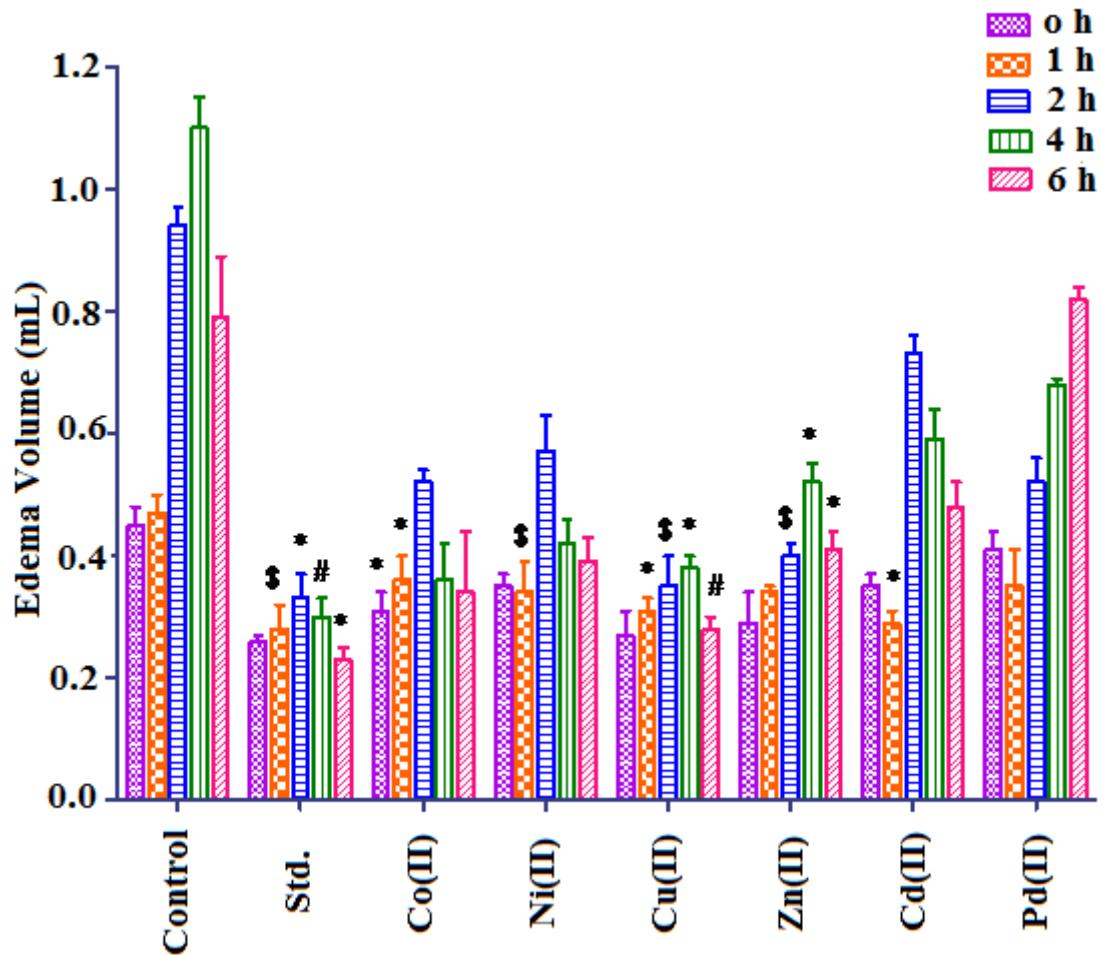

Fig. 3.17 The data are expressed as mean \pm SD. The level of significance were assigned as $^*p < 0.05$, $^{\$}p < 0.01$, $^{\#}p < 0.001$ compared to standard using unifactorial analysis of variance (ANOVA) followed by Dunnett's multiple comparison test

3.4 Molecular Docking

The ANA and its metal complexes Co(II), Ni(II), Cu(II), Zn(II), Cd(II) and Pd(II) bind strongly to the EGFR protein receptor by showing their minimum binding energies of -4.23 (ANA), -4.36, -4.64, -4.88, -5.79, -5.13, and -4.46 kcal/mol, respectively. When compared to the ligand, metal complexes interacted more effectively with the protein receptor, assuming that the ligand ANA in the complexes shows inclination to orient for the formation of grid protein. These binding energies in molecular docking studies strongly recommend *in vitro* anticancer activity results. The results are represented in Table 3.15 and Fig. 3.18. The docking results revealed that Zn(II) and Cd(II) complexes showed the least binding energies compared to other metal complexes against receptors EGFR with their binding energies of -5.79 and -5.13 kcal/mol. Hence EGFR was taken as the target protein receptors for an insightful and deep discussion into Zn(II) and Cd(II) complexes.

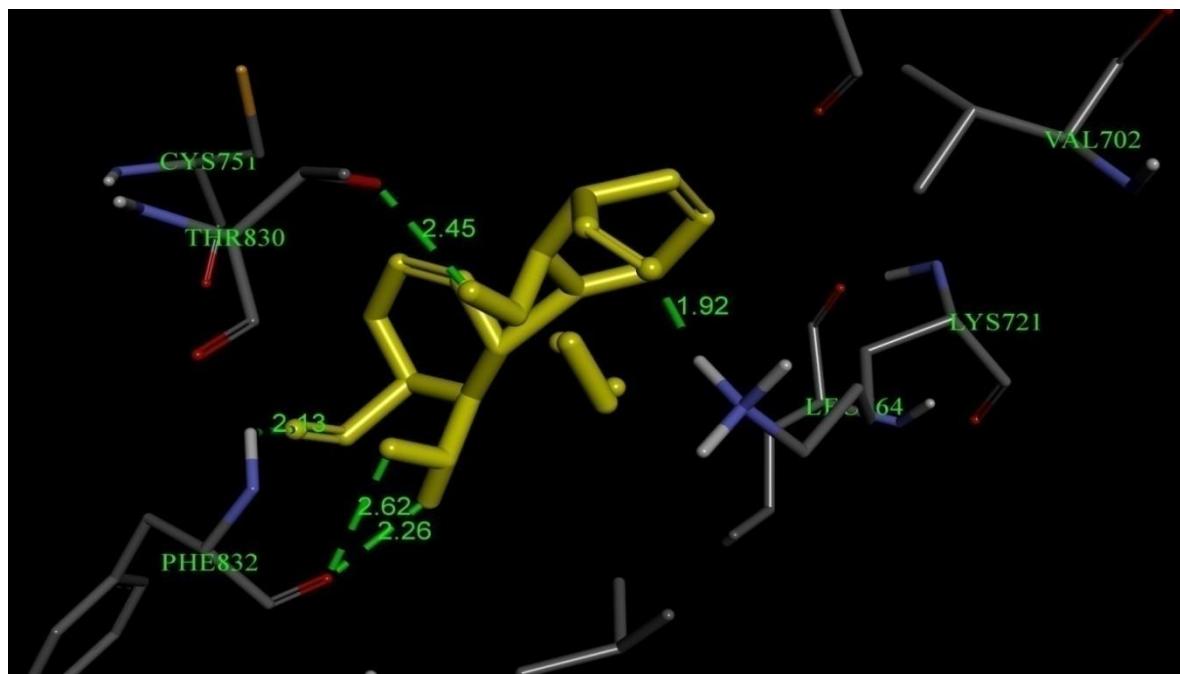

In Zn(II) complex, seven hydrogen bonds were observed between the ligands of metal complexes and EGFR protein receptor. Two hydrogen bonds, one with LYS721 and O-atom of the carbonyl group and the other with N atom of NH₂ group of one ANA having bond distances of 2.19 Å and 1.81 Å and bond angles of 132.27°, 139.32° in the complex were formed, One hydrogen bond with Arg817 and O-atom of carbonyl group having a bond distance 2.35 Å and a bond angle 117.14° was formed while another hydrogen bond was formed between ASN818 amino acid and hydrogen atom of NH₂ group with a bond distance of 2.34 Å, bond angle of 128.68° while the remaining three hydrogen bonds were formed with ASP831 amino acids. In that, two hydrogen atoms of NH₂ group were involved in bonding with bond distances of 2.05 Å and 2.72 Å, and bond angles of 105.86° and 98.12°, respectively, while another hydrogen bond was formed with hydrogen atoms of -NH₂ group of second ANA of the Zn(II) complex, with a bond distance of 1.93 Å and the bond angle of 135.44°. Among these hydrogen bonding interactions, Zn(II) complex forms some hydrophobic interactions with ARG817, ASN818, ASP831 and LYS721 amino acids.

In Cd(II) complex, two hydrogen bonds were formed when the ligand in the complex interacted strongly with protein receptor. One hydrogen bond was formed with ASP813 amino acid by interacting with H-atom of NH₂ group with a bond distance of 2.48 Å and bond angle of 124.53°, while another strong hydrogen bond was formed between ARG817 and N-atom of amine group with a bond distance of 2.15 Å and bond angle of 147.76°.

Besides these interactions, the complex had hydrophobic interactions with the following amino acids: ARG817 (2.89 Å), ASP813 (2.48 Å), LEU834, ALA835, ALA834, ALA698 and LYS851 amino acids.

3.5 Catalytic applications in MCR

The catalytic activity of Zn(II) complex was investigated by employing it as a catalyst in the synthesis of fully substituted pyridines and dihydropyrano[2,3-*c*]pyrazoles. Zn(II) complexes have several advantages, which can be justified as follows. Zinc is one of the highly abundant, cheap and low toxic metals in the periodic table. It can be easily separated or extracted in high purity from the corresponding minerals than many other metals. The biological relevance of zinc makes it an essential trace element to regulate enzymatic function of both animal and plant kingdom. Besides, at present, the current

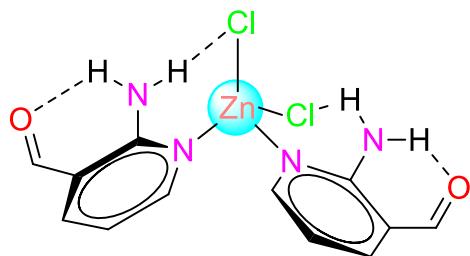

research in ‘green chemistry’ is focusing on the use of cheap and low toxic metals as catalysts or stoichiometric reagents to develop environmentally sustainable protocols in organic synthesis and pharmaceutical synthesis [49]. In line with these precedents, the use of zinc based catalysts (homogeneous/heterogeneous) and reagents would be a good choice to meet the requirements of green chemistry [49b,50].

Since the discovery of first organometallic diethyl zinc, a variety of catalytic and stoichiometric reagent applications of zinc compounds have been found in organic synthesis. For instance, the use of zinc in Negishi coupling, Reformatskii and Fukuyama reactions has been recognized as breakthrough reactions of organic synthesis [51,52]. However, as compared to other metals, the use of zinc compounds in organic synthesis is still at a developing stage due to its position in the periodic table that placed zinc between transition elements and main group elements. The filled d-orbital electronic configuration provides different chemistry to zinc than those of other d-block elements and more related chemistry to main group elements, which is quite simple and predictable. However, recent trends in green chemistry have strongly recommended the development of cheaper and low toxic zinc based organic transformations of C-C as well as C-heteroatom bond forming reactions for sustainable environment [49c,53].

The concept of multicomponent reaction (MCR) is one type of modern perspective emerged in green chemistry, wherein three or more than three components reacts in one-pot through sequential reactions and provide the desired product on a selective basis by reducing the waste. MCRs are indeed cost-effective, time-saving and environmentally benign as compared to step-by-step reactions of traditional organic synthesis in achieving the desired final product. A majority of MCRs require multifunctional catalyst to control the selectivity in the sequential reactions. At present, catalyzed MCRs are common practice to synthesize a variety of heterocycles and heteroatomic organic compounds [54].

We are interested in developing a facile MCR protocol to synthesize highly substituted pyridines and pyranopyrazole in view of their exciting applications in medicinal and materials chemistry. The use of a variety of homogeneous and heterogeneous catalysts has been reported previously to synthesize various densely substituted pyridines *via* traditional organic synthesis or MCR synthesis [55,56a,56b]

In this regard, $\text{Zn}(\text{ANA})_2\text{Cl}_2$ complex was chosen as a catalyst for the synthesis of a variety of fully substituted pyridines and dihydropyrano[2,3-*c*]pyrazoles.

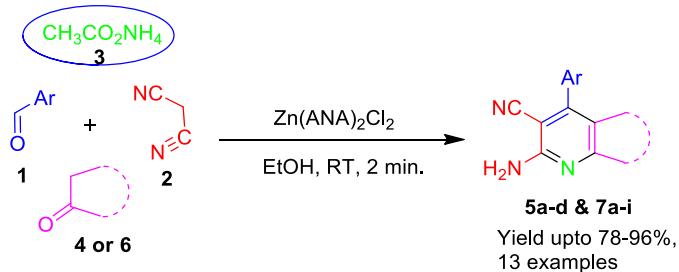

$[\text{Zn}(\text{ANA})_2\text{Cl}_2]$ complex

3.5.1 Synthesis of fully substituted pyridines

Initially, we chose to investigate a four component sequential one-pot reaction between malononitrile, ketone and ammonium acetate as partners to aromatic aldehydes to form a variety of fully substituted pyridines in environmentally friendly solvent ethanol (Scheme 1) under RT conditions. It is a matter of interest that the green aspect is connected not only with the use of water as reaction medium but also with the possibility to use other green solvents such as ethanol to improve yields and selectivity.

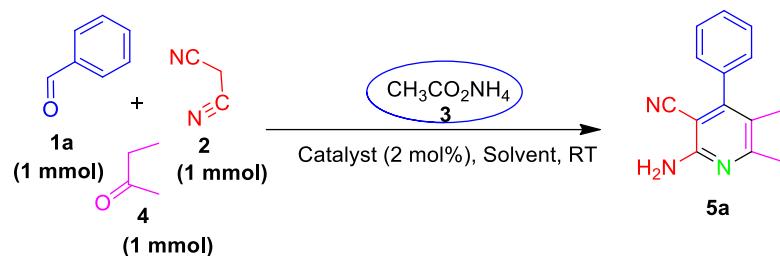

$\text{Zn}(\text{ANA})_2\text{Cl}_2$ complex was prepared on mixing freshly prepared solutions of ANA dissolved in 20 mL ethanol and $\text{ZnCl}_2 \cdot 4\text{H}_2\text{O}$ dissolved in 10 mL ethanol, at reflux temperature for about 3 h. At the end of the reaction, excess ethanol was removed in vacuum and filtered after cooling to obtain pure $\text{Zn}(\text{ANA})_2\text{Cl}_2$ complex. Further, by using $[\text{Zn}(\text{ANA})_2\text{Cl}_2]$ complex, the studies were extended to explore the catalytic ability of Zinc in MCR. It is worth noting that previously there were very few reports in the literature on the catalytic MCR synthesis of fully substituted pyridines. However, there was no information about the use of zinc catalysts in the MCR synthesis of fully substituted pyridines.

Scheme 1 Synthesis of fully substituted pyridines

Initially we chose to probe a four-component sequential one-pot reaction (MCR) between benzaldehyde (**1a**) malononitrile (**2**), ammonium acetate (**3**) and 2-butanone (**4**) (acyclic ketone) in ethanol in the presence of different zinc salts and a $\text{Zn}(\text{ANA})_2\text{Cl}_2$ complex for the synthesis of substituted pyridine **5a**. The details of the reaction and the results are given in Table 3.16.

Table 3.16 Optimization of reaction parameters for the synthesis of **5a**^a.

| Entry | Catalyst | Solvent | Temperature ^b | Yield (%) ^[c] |
|-------|--------------------------------------|---------|--------------------------|--------------------------|
| 1 | No Catalyst | EtOH | RT | -- |
| 2 | $\text{Zn}(\text{OAc})_2$ | EtOH | RT | 24 |
| 3 | $\text{Zn}(\text{OTf})_2$ | EtOH | RT | 36 |
| 4 | ZnCl_2 | EtOH | RT | 35 |
| 5 | $\text{Zn}(\text{NO}_3)_2$ | EtOH | RT | 30 |
| 6 | ZnBr_2 | EtOH | RT | 32 |
| 7 | $\text{Zn}(\text{BF}_4)_2$ | EtOH | RT | 35 |
| 8 | ZnI_2 | EtOH | RT | 35 |
| 9 | CuCl_2 | EtOH | RT | 28 |
| 10 | CuBr_2 | EtOH | RT | 26 |
| 11 | $\text{Zn}(\text{ANA})_2\text{Cl}_2$ | EtOH | RT | 92 |
| 12 | $\text{Zn}(\text{ANA})_2\text{Cl}_2$ | THF | RT | 22 |

| | | | | |
|----|--------------------------------------|--------------------|----|-------|
| 13 | Zn(ANA) ₂ Cl ₂ | CH ₃ CN | RT | 18 |
| 14 | Zn(ANA) ₂ Cl ₂ | DCM | RT | 20 |
| 15 | Zn(ANA) ₂ Cl ₂ | Dioxane | RT | Trace |
| 16 | Zn(ANA) ₂ Cl ₂ | Benzene | RT | Trace |

^aAll the reactions were carried out by using benzaldehyde **1a** (1 mmol), malononitrile **2** (1 mmol), ammonium acetate (**3**) and 2-butanone (**4**) (1 mmol) in water at room temperature to synthesize the compound **5a**. ^b Progress of the reaction was monitored by TLC. ^c Isolated yields.

The intended MCR was not observed in the absence of catalyst under RT conditions in ethanol (Table 3.16, entry 1). Later, we investigated the above MCR in the presence of different zinc salts including Zn(OAc)₂, Zn(OTf)₂, ZnCl₂, Zn(NO₃)₂, ZnBr₂, Zn(BF₄)₂, ZnI₂ (Table 3.16, entries 2-8) and copper salts CuCl₂ and CuBr₂ as catalysts (Table 3.16, entries 9, 10) under RT conditions. However, it was noticed that the simple zinc salts and copper salts did not facilitate the intended MCR under RT. In this situation, when Zn(ANA)₂Cl₂ was employed as a catalyst, there was a dramatic acceleration in the proposed MCR at RT which yielded the expected/desired substituted pyridine **5a** selectively just in 2 minutes in good yield (92%, Table 3.16, entry 11). It is also important to note that the above Zn(ANA)₂Cl₂ catalyzed reaction was observed to be sluggish and non-selective in non-protic solvents, THF, CH₃CN, DCM, Dioxane, Benzene (Table 3.16, entries 12-16). This information outlines that the choice of solvent is also one of the key factors in this catalyzed MCR.

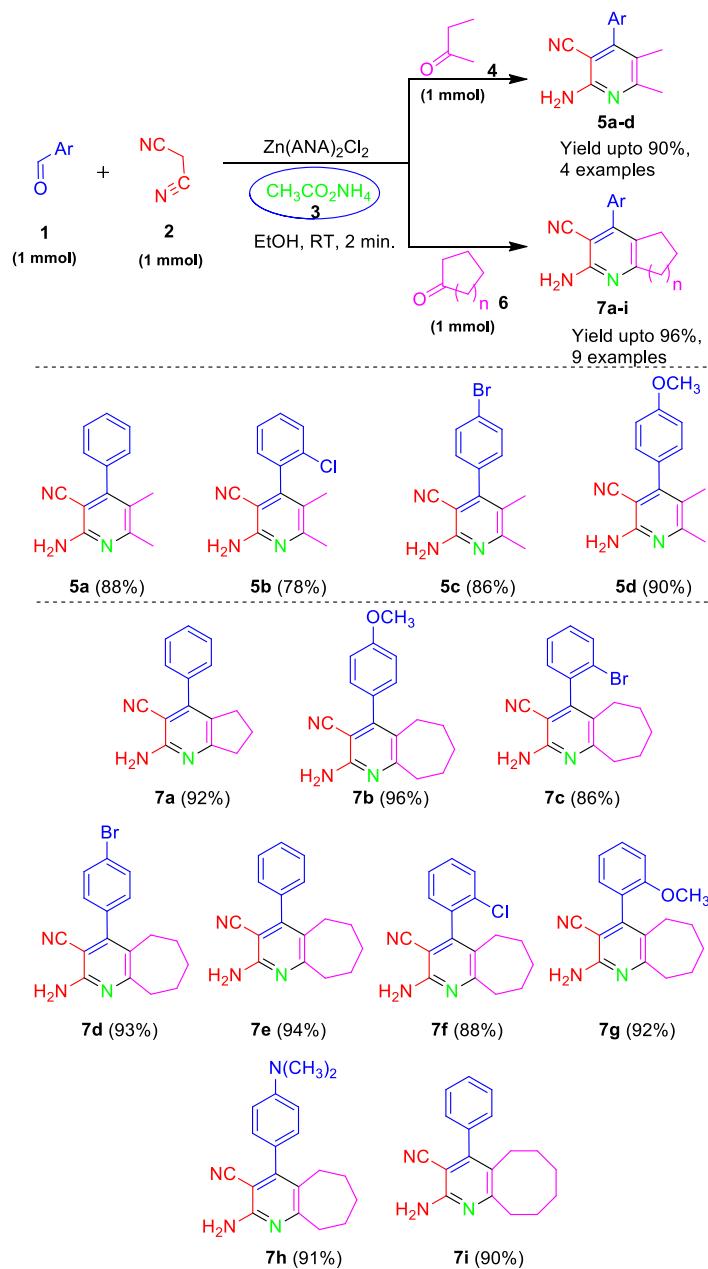

Table 3.17 Recyclability studies of the catalyst

| S. No. | Cycle No. | Reaction time (min.) ^a | Yield (%) ^b |
|--------|-----------|-----------------------------------|------------------------|
| 1 | 1 | 2 | 92 |
| 2 | 2 | 2 | 92 |
| 3 | 3 | 4 | 90 |
| 4 | 4 | 6 | 83 |
| 5 | 5 | 6 | 82 |

^aReaction progress was monitored by TLC, ^b Isolated yield

Literature reveals that there were few similar MCR strategies (malononitrile, ketone, ammonium acetate and aromatic aldehyde) developed with or without catalysts [56,57]. However, except the one that uses Ag(I)-NHC catalysts [56a], the remaining methodologies reported the requirement of refluxing or microwave conditions and longer reaction times [57]. Our results indicate the efficiency of zinc catalyst ($Zn(ANA)_2Cl_2$) in catalyzing MCR at just RT conditions to produce **5a** to meet the requirements of green catalysis. The solid product of **5a** obtained in our work was further identified and quantified on the basis of its analytical and spectral data. Using the above optimized conditions ($Zn(ANA)_2Cl_2$, 2 mol%, 2 min, RT, ethanol) for four-component MCR, we extended substrate scope to synthesize some diverse fully substituted pyridines. We have used various structurally different aldehydes (**1b-g**), acyclic ketones (**4**) and cyclic ketones (**6a-c**) in the MCR to study the electronic effects. The results are summarized in Scheme 2. The results indicate that $Zn(ANA)_2Cl_2$ is highly efficient in facilitating the MCRs of Scheme 2 and providing good yields in short reaction times. The substrates of MCR bearing electron donating or electron-withdrawing groups on the aromatic ring proceeded smoothly and formed the corresponding fully substituted pyridines in good yields.

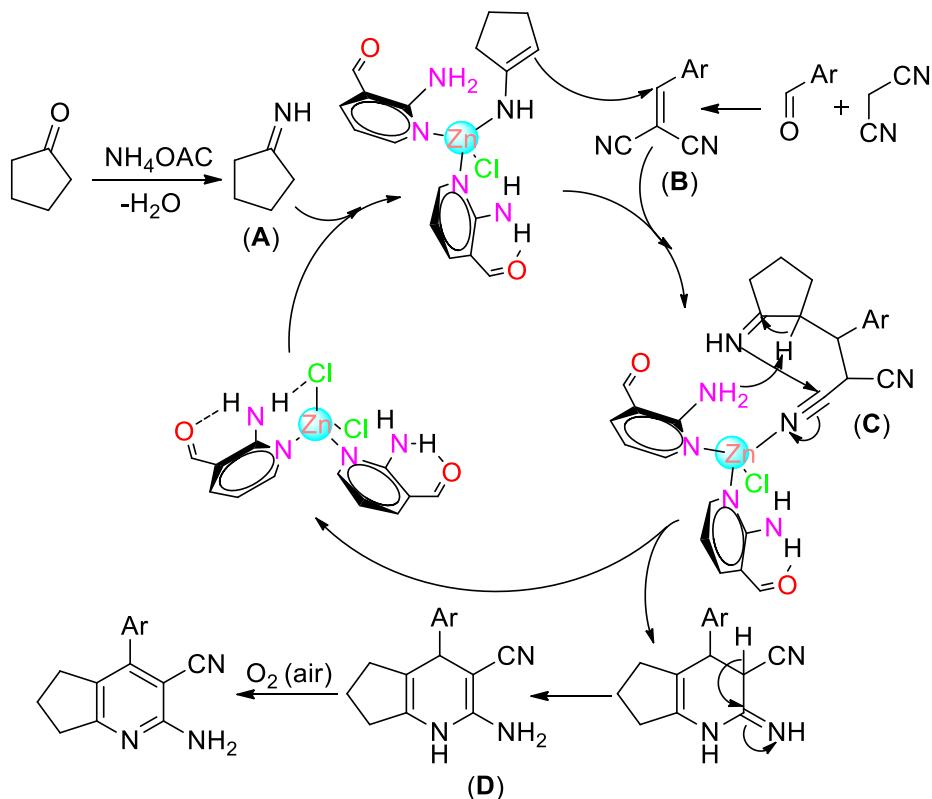

Structures of the substituted pyridines (**5a-d** & **7a-i**, Scheme 2) were established on the basis of elemental analysis and spectral data (1H and ^{13}C NMR).

Scheme 2 Synthesized fully substituted pyridine derivatives

Finally, based on the results obtained in our work and previous reports concerning the MCR synthesis of fully substituted pyridines including control experiments, a plausible mechanism has been deduced in Scheme 3. The reaction may proceed *via* forming enamine (**A**) the condensed product of ketone and ammonium acetate, then activated by $Zn(ANA)_2Cl_2$, which then reacts with alkylidenemalononitrile (**B**) (Knoevenagel condensed product of aldehyde with malononitrile) to give intermediate (**C**) (Michael adduct). The Michael adduct then undergoes cycloaddition and isomerization to give 1,4-dihydropyridine (**D**). The subsequent oxidative aromatization of

1,4-dihydropyridine (**D**) under air atmosphere will produce the desired fully substituted pyridines (**5a-d & 7a-i**) as shown in Scheme 3.

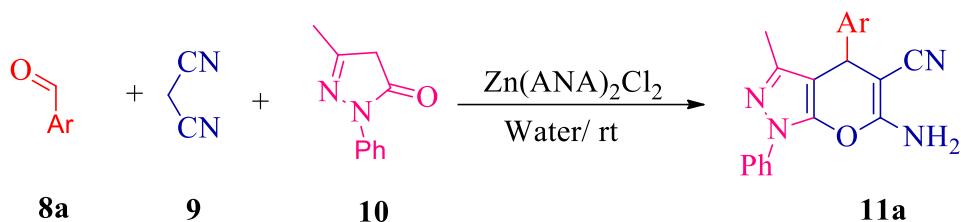

Scheme 3 A plausible mechanism for the formation fully substituted pyridines

3.5.2 Synthesis of substituted dihydropyrano[2,3-c]pyrazoles

In preliminary experiments, the three-component sequential one-pot reaction (MCR) between benzaldehyde (**8a**), malononitrile (**9**), and 3-methyl-1-phenyl-2-pyrazoline-5-one (**10**), in water as a solvent at room temperature, and the scope of a variety of potential catalyst materials. The details of the reaction and the results are given in Table 3.18. There was no MCR sequence observed without any catalyst (Table 3.18, entry 1). Later, the above MCR was investigated in the presence of different zinc and copper salts including $\text{Zn}(\text{BF}_4)_2$, $\text{Zn}(\text{OTf})_2$, ZnBr_2 , $\text{Zn}(\text{NO}_3)_2$, (Table 3.18, entries 2-5) and copper salts $\text{Cu}(\text{OAc})_2$ and CuBr_2 as catalysts (Table 3.18, entries 6,7) at RT conditions. However, when 5 mol% of $\text{Zn}(\text{ANA})_2\text{Cl}_2$ was employed as catalyst, product **11a** (Scheme 4) formed with a yield 79% in 12 min. (Table 3.18, entry 8). After that, the same reaction was carried out by using 10, 15 and 20 mol % of $\text{Zn}(\text{ANA})_2\text{Cl}_2$ catalyst, the results were impressive producing the substituted dihydropyrano[2,3-c]pyrazoles (**11a**) selectively and at room temperature in good yields at different times (Table 3.18, entries 8-11). The catalyst with 10 mol% was the best catalyst in water resulting in high yields with low

reaction time (Table 3.18, entry 9). Continuing the work, we have also investigated the above MCR to get the optimized reaction condition, the reaction further proceeded with 10 mol% of $\text{Zn}(\text{ANA})_2\text{Cl}_2$ catalyst for 30 min. (Table 3.18, entry 12) without any increase yields. There was also no progress in the above MCR when carried out at different temperatures (Table 3.18, entries 13,14). The catalyzed MCRs of present study in water are found to be slightly exothermic in the beginning as observed in other works. It is also important to note that the above catalyzed reaction was observed to be sluggish and non-selective in non-protic solvents; THF, CH_3CN , and CH_2Cl_2 and finally ended up with a mixture of products. This information outlines that the choice of solvent is also one of the key factors in the catalyzed MCR.

Scheme 4 The synthetic pathway of compounds **11a**

Table 3.18 Optimization of reaction conditions for the synthesis **11a**^a

| Entry | Catalyst (mol%) | Temperature (°C) | Time ^b | Yield (%) ^c |
|-------|--|------------------|-------------------|------------------------|
| 1 | No Catalyst | rt | 60 min. | Trace |
| 2 | $\text{Zn}(\text{BF}_4)_2$ | rt | 45 min. | 40 |
| 3 | $\text{Zn}(\text{OTf})_2$ | rt | 45 min. | 35 |
| 4 | ZnBr_2 | rt | 30 min. | 25 |
| 5 | $\text{Zn}(\text{NO}_3)_2$ | rt | 30 min. | 35 |
| 6 | $\text{Cu}(\text{OAc})_2$ | rt | 30 min. | Trace |
| 7 | CuBr_2 | rt | 30 min. | Trace |
| 8 | $\text{Zn}(\text{ANA})_2\text{Cl}_2$ (5 mol%) | rt | 12 min. | 79 |
| 9 | $\text{Zn}(\text{ANA})_2\text{Cl}_2$ (10 mol%) | rt | 5 min. | 88 |
| 10 | $\text{Zn}(\text{ANA})_2\text{Cl}_2$ (15 mol%) | rt | 8 min. | 85 |
| 11 | $\text{Zn}(\text{ANA})_2\text{Cl}_2$ (20 mol%) | rt | 7 min. | 85 |
| 12 | $\text{Zn}(\text{ANA})_2\text{Cl}_2$ (10 mol%) | rt | 10 min. | 88 |

| | | | | |
|----|--|----|--------|----|
| 13 | Zn(ANA) ₂ Cl ₂ (10 mol%) | 60 | 5 min. | 83 |
| 14 | Zn(ANA) ₂ Cl ₂ (10 mol%) | 80 | 5 min. | 80 |

^a All the reactions were carried out by using benzaldehyde **8a** (1 mmol), malononitrile **9** (1 mmol) and 3-methyl-1-phenyl-2-pyrazoline-5-one **10** (1 mmol) in water at room temperature to synthesize the compound **11a**. ^b Progress of the reaction was monitored by TLC. ^c Isolated yields.

In order to recycle Zn(ANA)₂Cl₂, the reaction mixture was filtered and the residue was quenched two times with ethyl acetate to separate the crude product after the first catalytic run. The water layers dried and were reused for the next catalytic runs. It has been noticed that up to four successive catalytic yields of dihydropyrano[2,3-c]pyrazoles are almost in the close range (entries 1-4 of Table 3.18) and there was no considerable agglomeration of Zn(ANA)₂Cl₂. However, the yields were slowly reduced from the fifth cycle (entry 5 of Table 3.18) due to increase in operation time. This is attributed to the decrease of multi-component activity of the catalyst due to the percentage of catalyst and metal deposition, which inhibits the activity of active sites of the catalyst. The recyclability studies of the catalyst and the derivatives of the compounds (**11a-l**) are shown in Table 3.18 and 3.19.

Table 3.19 Recyclability studies of the catalyst (Zn(ANA)₂Cl₂ complex)

| S. No. | Cycle No. | Reaction time (min.) ^a | Yield (%) ^b |
|--------|-----------|-----------------------------------|------------------------|
| 1 | 1 | 5 | 86 |
| 2 | 2 | 5 | 86 |
| 3 | 3 | 8 | 85 |
| 4 | 4 | 8 | 85 |
| 5 | 5 | 10 | 80 |

^a All the reactions were carried out by using aromatic aldehydes **8a-l**, 3-methyl-1-phenyl-2-pyrazoline-5-one **9** and malononitrile **10** as starting material in water with the $\text{Zn(ANA)}_2\text{Cl}_2$ complex as catalyst. ^b Progress of the reaction was monitored by TLC. ^c Isolated yields (%).

Employing the same reaction conditions for the synthesis of **11a** (RT, $\text{Zn}(\text{ANA})_2\text{Cl}_2$ (10 mol%, 5 min, water), we investigated the scope of the reaction with a variety of structurally different aldehydes (**8b-l**) in combination with malononitrile (**9**) and 3-methyl-1-phenyl-2-pyrazoline-5-one (**10**) for the three component condensation reaction. The results are depicted in Table 3.19. The substrates of MCR bearing electron donating or electron-withdrawing groups on the aromatic ring proceeded smoothly and formed the corresponding substituted dihydropyrano[2,3-c]pyrazoles in good yields (85-95%) under the chosen conditions. This reaction was considered as a green reaction because of its mild reaction condition, use of environmentally benign solvent and reusable catalyst.

Scheme 5 Possible mechanism for the formation of Pyranopyrazole *via* catalyzed by $\text{Zn}(\text{ANA})_2\text{Cl}_2$

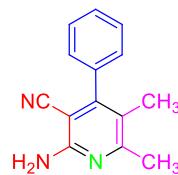

Based on previous reports and current results in the MCR synthesis of Pyranopyrazole, a plausible mechanism is proposed and depicted in Scheme 5 which involves a domino Michael addition-tautomerism-*O*-cyclization sequence of reactions. The reaction may proceed *via* forming chelation between phenylmethylpyrazolone and $\text{Zn}(\text{ANA})_2\text{Cl}_2$ complex (A) and which then reacts with alkylidenemalononitrile (B) (Knoevenagel condensed product of aldehyde with malononitrile) to give intermediate (C) (Michael adduct). The Michael adduct then undergoes *O*-cyclization to give Pyranopyrazoles.

3.6.1 General procedure for the synthesis of pyridines (5a-d & 7a-i)

Aromatic aldehydes (**1**) (1 mmol) and malononitrile (1 mmol) was dissolved in EtOH (10 mL) and added the ethanolic solution of cyclic ketone/ethyl methyl ketone (**2a-c** or **2d**) (1.2 mmol), ammonium acetate (1.2 mmol) and catalyst Zn(ANA)₂Cl₂ (2 mol%) were stirred over a period of 2 min. at room temperature. Complete consumption of starting material as judged by TLC and GC analysis. The reaction mass was filtered and washed with ethanol to obtained off-white solid crude product which was subjected to recrystallization in hot ethyl acetate to afford pure products (**5a-d & 7a-i**).

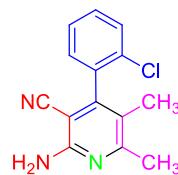

3.6.2 Spectral data of Pyridine compounds (5a-d & 7a-i)

2-Amino-5,6-dimethyl-4-phenyl-nicotinonitrile (5a)

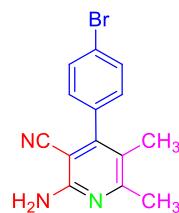

The product was obtained as off-white solid. Yield: 88%. M.p.: 240-241 °C. ¹H NMR (400 MHz, CDCl₃): δ, ppm 1.95 (s, 3H, CH₃), 2.44 (s, 3H, CH₃), 5.05 (s, 2H, NH₂), 7.23-7.50 (m, 5H). ¹³C NMR (100 MHz, CDCl₃): δ, ppm 15.30, 23.72, 89.72, 116.80, 119.69, 128.33, 128.64, 128.77, 136.79, 153.86, 157.23, 161.57. Anal. Calcd. (%) for C₁₄H₁₃N₃: C, 75.31; H, 5.87; N, 18.82. Found: C, 75.37; H, 5.89; N 18.78.

2-Amino-4-(2-chloro-phenyl)-5,6-dimethyl-nicotinonitrile (5b)

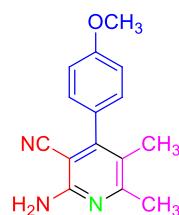

The product was obtained as off-white solid. Yield: 78%. M.p.: 251-252 °C. ¹H NMR (400 MHz, CDCl₃): δ, ppm 1.88 (s, 3H, CH₃), 2.46 (s, 3H, CH₃), 5.03 (s, 2H, NH₂), 7.17-7.53 (m, 4H). ¹³C NMR (100 MHz, CDCl₃): δ, ppm 14.89, 23.66, 116.20, 120.43, 127.0, 127.22, 129.81, 129.94, 130.16, 130.30, 132.45, 151.14, 157.13, 161.71. Anal. Calcd. (%) for C₁₄H₁₂ClN₃: C, 65.25; H, 4.69; N, 16.30. Found: C, 65.29; H, 4.74; N, 16.36.

2-Amino-4-(4-bromo-phenyl)-5,6-dimethyl-nicotinonitrile (5c)

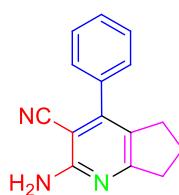

The product was obtained as off-white solid. Yield: 86%. M.p.: 265-266 °C. ^1H NMR (400 MHz, CDCl_3): δ , ppm 1.94 (s, 3H, CH_3), 2.44 (s, 3H, CH_3), 5.02 (s, 2H, NH_2), 7.11 (d, J = 8.2 Hz, 2H), 7.63 (d, J = 8.1 Hz, 2H). ^{13}C NMR (100 MHz, CDCl_3): δ , ppm 15.3, 23.79, 89.94, 112.48, 119.53, 129.72, 130.07, 131.98, 132.12, 153.68, 157.23, 161.92. Anal. Calcd. (%) for $\text{C}_{14}\text{H}_{12}\text{BrN}_3$: C, 55.65; H, 4.0; N, 13.91. Found: C, 55.57; H, 4.04; N, 13.87.

2-Amino-4-(4-methoxy-phenyl)-5,6-dimethyl-nicotinonitrile (5d)

The product was obtained as off-white solid. Yield: 90%. M.p.: 276-277 °C. ^1H NMR (400 MHz, CDCl_3): δ , ppm 1.97 (s, 3H, CH_3), 2.44 (s, 3H, CH_3), 3.86 (s, 3H, OCH_3), 5.0 (s, 2H, NH_2), 6.98 (d, J = 8.5 Hz, 2H), 7.17 (d, J = 8.5 Hz, 2H). ^{13}C NMR (100 MHz, CDCl_3): δ , ppm 15.36, 23.78, 55.29, 89.94, 114.05, 119.95, 128.90, 129.58, 129.81, 153.68, 157.25, 159.89, 161.46. Anal. Calcd. (%) for $\text{C}_{15}\text{H}_{15}\text{N}_3\text{O}$: C, 71.13; H, 5.97; N, 16.59. Found: C, 71.18; H, 5.99; N, 16.64.

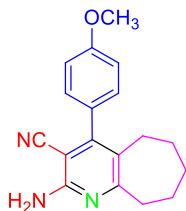

2-Amino-4-phenyl-6,7-dihydro-5*H*-cyclopenta[b]pyridine-3-carbonitrile (7a)

The product was obtained as off-white solid. Yield: 92%. M.p.: 220-221 °C. ^1H NMR (400 MHz, CDCl_3): δ , ppm 1.90-1.98 (m, 2H), 2.60 (t, J = 7.3 Hz, 2H), 2.80 (t, J = 7.6 Hz, 2H), 6.66 (s, 2H, NH_2), 7.42-7.51 (m, 5H). ^{13}C NMR (100 MHz, CDCl_3): δ , ppm 22.22, 28.78, 34.50, 85.52, 117.39, 123.02, 128.24, 128.49, 128.92, 135.92, 149.16,

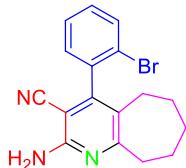

160.99, 169.64. Anal. Calcd. (%) for $C_{15}H_{13}N_3$: C, 76.57; H, 5.57; N, 17.86. Found. C, 76.59; H, 5.58; N, 17.89.

2-Amino-4-(4-methoxy-phenyl)-6,7,8,9-tetrahydro-5*H*-cyclohepta[b]pyridine-3-carbonitrile (7b)

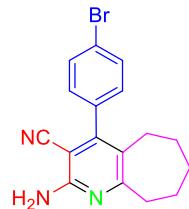

The product was obtained as off-white solid. Yield: 96%. M.p.: 223-224 °C. 1H NMR (400 MHz, $CDCl_3$): δ , ppm 1.48-1.53 (m, 2H), 1.70-1.84 (m, 4H), 2.49 (t, J = 5.4 Hz, 2H), 2.91 (t, J = 5.4 Hz, 2H), 3.85 (s, 3H, OCH_3), 5.07 (s, 2H, NH_2), 6.98 (d, J = 8.6, 2H), 7.15 (d, J = 8.6, 2H). ^{13}C NMR (100 MHz, $CDCl_3$): δ , ppm 26.20, 28.06, 28.91, 32.0, 39.69, 55.28, 89.59, 114.03, 117.21, 126.69, 128.97, 129.82, 152.94, 157.24, 159.82, 167.86. Anal. Calcd. (%) for $C_{18}H_{19}N_3O$: C, 73.69; H, 6.53; N, 14.32. Found: C, 73.72; H, 6.55; N, 14.39.

2-Amino-4-(2-bromo-phenyl)-6,7,8,9-tetrahydro-5*H*-cyclohepta[b]pyridine-3-carbonitrile (7c)

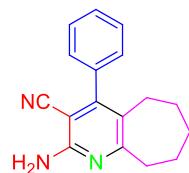

The product was obtained as off-white solid. Yield: 86%. M.p.: 261-262 °C. 1H NMR (400 MHz, $CDCl_3$): δ , ppm 1.38-3.0 (m, 10H), 5.14 (s, 2H, NH_2), 7.14-7.70 (m, 4H). ^{13}C NMR (100 MHz, $CDCl_3$): δ , ppm 26.11, 27.54, 29.27, 32.01, 39.80, 89.17, 116.28, 122.30, 126.58, 127.71, 129.79, 130.29, 133.03, 137.91, 151.86, 157.13, 168.14. Anal. Calcd. (%) for $C_{17}H_{16}BrN_3$: C, 59.66; H, 4.71; N, 12.28. Found: C, 59.69; H, 4.76; N, 12.32.

2-Amino-4-(4-bromo-phenyl)-6,7,8,9-tetrahydro-5*H*-cyclohepta[b]pyridine-3-carbonitrile (7d)

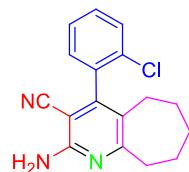

The product was obtained as off-white solid. Yield: 93%. M.p.: 236-237 °C. ¹H NMR (400 MHz, CDCl₃): δ, ppm 1.48-1.51 (m, 2H), 1.70-1.84 (m, 4H), 2.44 (t, *J* = 5.4 Hz, 2H), 2.92 (t, *J* = 5.4 Hz, 2H), 5.14 (s, 2H, NH₂), 7.10 (d, *J* = 8.3, 2H), 7.60 (d, *J* = 8.3, 2H). ¹³C NMR (100 MHz, CDCl₃): δ, ppm 26.14, 27.99, 28.97, 31.92, 39.67, 88.90, 116.76, 123.13, 126.26, 130.10, 131.93, 135.68, 151.73, 157.26, 168.25. Anal. Calcd. (%) for C₁₇H₁₆BrN₃: C, 59.66; H, 4.71; N, 12.28. Found: C 59.74, H 4.68, N 12.35.

2-Amino-4-phenyl-6,7,8,9-tetrahydro-5*H*-cyclohepta[b]pyridine-3-carbonitrile (7e)

The product was obtained as off-white solid. Yield: 94%. M.p.: 227-228 °C. ¹H NMR (400 MHz, CDCl₃): δ, ppm 1.47-1.52 (m, 2H), 1.69-1.82 (m, 4H), 2.46 (t, *J* = 5.4 Hz, 2H), 2.92 (t, *J* = 5.5 Hz, 2H), 5.11 (s, 2H, NH₂), 7.21-7.49 (m, 5H). ¹³C NMR (100 MHz, CDCl₃): δ, ppm 26.18, 28.03, 28.97, 31.98, 39.67, 89.33, 116.94, 126.42, 128.38, 128.60, 128.68, 136.85, 153.11, 157.22, 167.96. Anal. Calcd. (%) for C₁₇H₁₇N₃: C, 77.54; H, 6.51; N, 15.96. Found: C, 77.62; H, 6.49; N, 15.98.

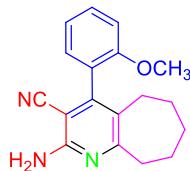

2-Amino-4-(2-chloro-phenyl)-6,7,8,9-tetrahydro-5*H*-cyclohepta[b]pyridine-3-carbonitrile (7f)

The product was obtained as off-white solid. Yield: 88%. M.p.: 273-274 °C. ¹H NMR (400 MHz, CDCl₃): δ, ppm 1.39-2.96 (m, 10H), 5.18 (s, 2H, NH₂), 7.15-7.52 (m, 4H). ¹³C NMR (100 MHz, CDCl₃): δ, ppm 26.11, 27.57, 29.27, 32.01, 39.77, 89.24, 116.34,

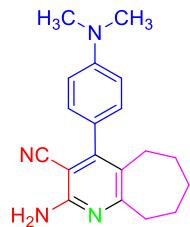

126.78, 127.12, 129.87, 129.91, 130.20, 132.58, 135.81, 150.33, 157.21, 168.07. Anal. Calcd. (%) for $C_{17}H_{16}ClN_3$: C, 68.57; H, 5.42; N, 14.11. Found: C, 68.65; H, 5.46; N, 14.09.

2-Amino-4-(2-methoxy-phenyl)-6,7,8,9-tetrahydro-5*H*-cyclohepta[b]pyridine-3-carbonitrile (7g)

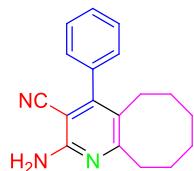

The product was obtained as off-white solid. Yield: 92%. M.p.: 244-245 °C. 1H NMR (400 MHz, $CDCl_3$): δ , ppm 1.42-2.94 (m, 10H), 3.78 (s, 3H, OCH_3), 5.03 (m, 2H, NH_2), 6.99-7.43 (m, 4H). ^{13}C NMR (100 MHz, $CDCl_3$): δ , ppm 26.18, 27.65, 29.40, 32.13, 39.76, 55.46, 90.08, 111.11, 117.03, 120.74, 125.59, 127.36, 130.0, 130.39, 150.33, 156.11, 157.16, 167.37. Anal calcd. (%) for $C_{18}H_{19}N_3O$: C, 73.69; H, 6.53; N, 14.32. Found: C, 73.62; H, 6.56; N, 14.30.

2-Amino-4-(4-dimethylamino-phenyl)-6,7,8,9-tetrahydro-5*H*-cyclohepta[b]pyridine-3-carbonitrile (7h)

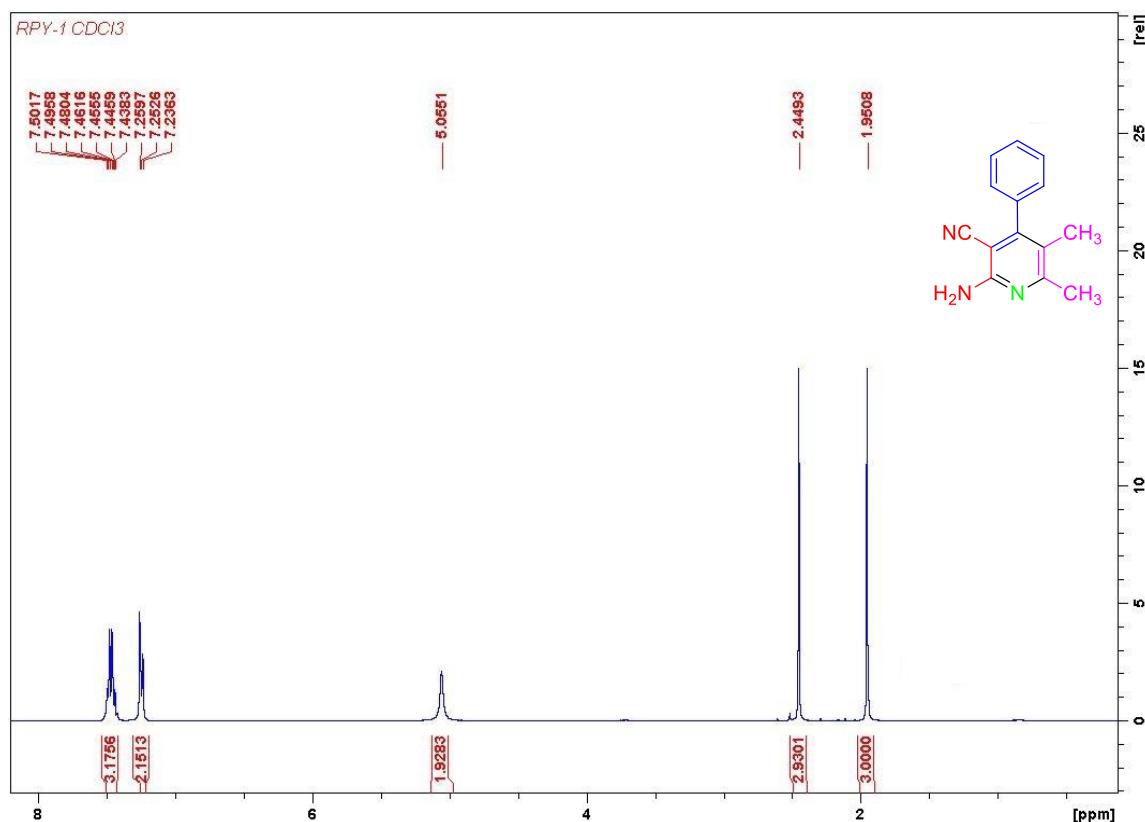

The product was obtained as light yellow solid. Yield: 91%. M.p.: 230-231 °C. 1H NMR (400 MHz, $CDCl_3$): δ , ppm 1.52-1.81 (m, 6H), 2.56 (t, J = 5.3 Hz, 2H), 2.91 (t, J = 5.4 Hz, 2H), 3.01 (s, 6H, $N(CH_3)_2$), 4.96 (s, 2H, NH_2), 6.76 (d, J = 8.6 Hz, 2H), 7.11 (d, J = 8.6 Hz, 2H). ^{13}C NMR (100 MHz, $CDCl_3$): δ , ppm 26.25, 28.15, 28.90, 32.06, 39.73, 40.26, 88.90, 111.77, 123.13, 124.04, 126.79, 129.63, 135.68, 150.42, 153.68, 157.28, 167.58. 3.6.3 General procedure for the synthesis of the dihydropyrano[2,3-c]pyrazoles (11a-l)

A mixture of aromatic aldehydes (1 mmol), malononitrile (1 mmol) and 3-methyl-1-phenyl-2-pyrazoline-5-one (1 mmol) was stirred in water at room temperature in the presence of 10 mol% of $\text{Zn}(\text{ANA})_2\text{Cl}_2$ complex for appropriate time to produce dihydropyrano[2,3-c]pyrazoles. Reaction progress was monitored by TLC. After completion of the reaction, the product was filtered. The residue was washed with ethyl acetate. Ethyl acetate was evaporated under vacuum and the obtained solid was purified by recrystallization process in ethyl acetate.

3.6.4 Spectral data of the compounds 11a-l

6-amino-3-methyl-1,4-diphenyl-1,4-dihydropyrano[2,3-c]pyrazole-5-carbonitrile (11a)

Colour: White solid. M.p.: 168-170 °C. ^1H NMR (400 MHz, $\text{DMSO}-d_6$): δ , ppm 1.79 (s, 3H, CH_3), 4.89 (s, 1H), 7.22-7.36 (m, 8H), 7.5 (d, 2H, J = 7.6 Hz), 7.8 (d, 2H, J = 7.6 Hz). ^{13}C

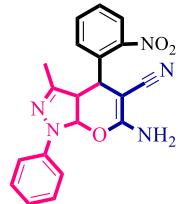

NMR (100 MHz, DMSO-*d*₆): δ , ppm 159.90, 145.75, 144.36, 144.08, 138.02, 129.80, 129.00, 128.25, 127.52, 126.63, 120.43, 99.11, 58.68, 37.23, 13.03. Anal. Calcd. for C₂₀H₁₆N₄O: C, 73.15; H, 4.91; N, 17.06. Found: C, 73.37; H, 4.98; N, 17.29.

6-amino-3-methyl-4-(3-nitrophenyl)-1-phenyl-1,4-dihydropyrano[2,3-c]pyrazole-5-carbonitrile (11b)

Colour: White solid. M.p.: 187-189 °C. ¹H NMR (400 MHz, DMSO-*d*₆): δ , ppm 1.81 (s, 3H), 4.99 (s, 1H), 7.34 (t, 1H, *J* = 7.2 Hz), 7.42 (s, 2H), 7.51 (t, 2H, *J* = 7.6 Hz), 7.69 (t, 1H, *J* = 8.4 Hz), 7.79- 7.82 (m, 3H), 8.17 (bs, 2H). ¹³C NMR (100 MHz, DMSO-*d*₆): δ , ppm 160.23, 148.42, 146.45, 145.63, 144.50, 137.91, 135.25, 130.76, 129.80, 129.39, 126.77, 122.76, 122.73, 120.58, 120.28, 98.13, 57.53, 36.67, 13.08. Anal. Calcd. (%) for C₂₀H₁₅N₅O₃: C, 64.34; H, 4.05; N, 18.76. Found: C, 64.59; H, 4.11; N, 18.49.

6-amino-3-methyl-4-(2-nitrophenyl)-1-phenyl-1,4-dihydropyrano[2,3-c]pyrazole-5-carbonitrile (11c)

Colour: White solid. M.p.: 156-158 °C. ¹H NMR (400 MHz, DMSO-*d*₆): δ , ppm 1.76 (s, 3H), 5.21 (s, 1H), 7.32-7.39 (m, 3H), 7.49-7.56 (m, 4H), 7.7 (t, 1H, *J* = 7.6 Hz), 7.8 (d, 2H, *J* = 8.00 Hz), 7.91 (d, 1H, *J* = 8.00 Hz). ¹³C NMR (100 MHz, DMSO-*d*₆): δ , ppm 160.26, 149.75, 147.25, 145.36, 144.83, 138.18, 137.89, 137.17, 133.89, 132.12, 129.82, 129.11, 126.82, 124.19, 120.59, 119.96, 97.78, 57.28, 32.38, 12.75. Anal. Calcd. (%) for C₂₀H₁₅N₅O₃: C, 64.34; H, 4.05; N, 18.76. Found: C, 64.02; H, 4.15; N, 18.98.

6-amino-4-(3,4-dimethylphenyl)-3-methyl-1-phenyl-1,4-dihydropyrano[2,3-c]pyrazole-5-carbonitrile (11d)

Colour: White solid. M.p.: 150-151 °C. ^1H NMR (400 MHz, DMSO- d_6): δ , ppm 1.82 (s, 3H), 3.72 (s, 3H), 3.74 (s, 3H), 4.64 (s, 1H), 6.75-6.93 (m, 3H), 7.17 (s, 2H) 7.32 (t, 1H, J = 7.2 Hz), 7.49 (t, 2H, J = 7.6 Hz), 7.79 (d, 2H, J = 8.00 Hz). ^{13}C NMR (100 MHz, DMSO- d_6): δ , ppm 159.80, 149.09, 148.28, 145.86, 144.27, 138.07, 136.52, 129.79, 126.57, 120.55, 120.35, 112.26, 112.03, 99.18, 58.90, 56.04, 55.93, 36.65, 13.15. Anal. Calcd. (%) for $\text{C}_{22}\text{H}_{20}\text{N}_4\text{O}$: C, 74.14; H, 5.66; N, 15.72. Found: C, 74.39; H, 5.75; N, 15.51.

6-amino-4-(4-cyanophenyl)-3-methyl-1-phenyl-1,4-dihydropyrano[2,3-c]pyrazole-5-carbonitrile (11e)

Colour: White solid. M.p.: 198-200 °C. ^1H NMR (400 MHz, DMSO- d_6): δ , ppm 1.79 (s, 3H), 4.85 (s, 1H), 7.34 (t, 1H, J = 7.2 Hz), 7.39 (s, 2H), 7.49-7.52 (m, 4H), 7.80-7.86(m, 4H). ^{13}C NMR (100 MHz, DMSO- d_6): δ , ppm 160.17, 149.66, 145.59, 144.50, 137.92, 133.11, 129.79, 129.43, 126.75, 120.57, 120.25, 119.24, 110.43, 98.11, 57.50, 37.13, 13.01. Anal. Calcd. (%) for $\text{C}_{21}\text{H}_{15}\text{N}_5\text{O}$: C, 71.38; H, 4.28; N, 19.82. Found: C, 71.62; H, 4.34; N, 19.69.

6-amino-4-(4-hydroxyphenyl)-3-methyl-1-phenyl-1,4-dihydropyrano[2,3-c]pyrazole-5-carbonitrile (11f)

Colour: White solid. M.p.: 205-207 °C. ^1H NMR (400 MHz, DMSO- d_6): δ , ppm 1.81 (s, 3H), 4.57 (s, 1H), 6.76 (s, 2H), 7.06 (s, 2H), 7.17 (s, 2H), 7.31(s, 1H), 7.49 (s, 2H), 7.80 (s, 2H), 9.39 (s, 1H). ^{13}C NMR (100 MHz, DMSO- d_6): δ , ppm 159.67, 156.77, 145.84, 144.24, 138.07, 134.41, 129.78, 129.26, 126.52, 120.62, 120.33, 115.70, 99.50, 59.27, 36.50, 19.03. Anal. Calcd. (%) for $\text{C}_{20}\text{H}_{16}\text{N}_4\text{O}_2$: C, 69.76; H, 4.68; N, 16.27. Found: C, 69.91; H, 4.75; N, 16.11.

6-amino-4-(4-chlorophenyl)-3-methyl-1-phenyl-1,4-dihydropyrazole-5-carbonitrile (11g)

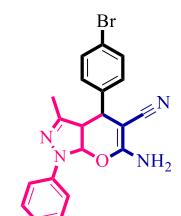

Colour: Pale yellow solid. M.p.: 176-178 °C. ¹H NMR (400 MHz, DMSO-*d*₆): δ, ppm 1.82 (s, 3H), 4.73 (s, 1H), 7.27-7.34 (m, 5H), 7.42 (d, 2H, *J* = 8.00 Hz), 7.5 (t, 2H, *J* = 7.2 Hz), 7.8 (d, 2H, *J* = 7.6 Hz). ¹³C NMR (100 MHz, DMSO-*d*₆): δ, ppm 159.95, 145.67, 144.40, 143.14, 137.97, 132.06, 130.18, 129.80, 129.01, 126.69, 120.50, 120.34, 98.66, 58.24, 36.56, 13.04. Anal. Calcd. (%) for C₂₀H₁₅ClN₄O: C, 66.21; H, 4.17; N, 15.44. Found: C, 66.43; H, 4.10; N, 15.19.

6-amino-4-(2,4-dichlorophenyl)-3-methyl-1-phenyl-1,4-dihydropyrazole-5-carbonitrile (11h)

Colour: White solid. M.p.: 183-185 °C. ¹H NMR (400 MHz, DMSO-*d*₆): δ, ppm 1.78 (s, 3H), 5.16 (s, 1H), 7.32 (d, 1H), 7.36 (s, 2H,), 7.39-7.63 (m, 5H,), 7.78-7.80 (d, 2H). ¹³C NMR (100 MHz, DMSO-*d*₆): δ, ppm 160.42, 145.30, 144.75, 139.74, 137.90, 133.55, 133.02, 132.97, 30.54, 129.82, 129.43, 128.59, 126.78, 120.53, 120.01, 97.76, 56.62, 34.02, 12.82. Anal. Calcd. (%) for C₂₀H₁₄Cl₂N₄O: C, 60.47; H, 3.55; N, 14.10. Found: C, 60.69; H, 3.49; N, 14.39.

6-amino-4-(4-bromophenyl)-3-methyl-1-phenyl-1,4-dihydropyrazole-5-carbonitrile (11i)

Colour: White solid. M.p.: 182-184 °C. ¹H NMR (400 MHz, DMSO-*d*₆): δ, ppm 1.8 (s, 3H), 4.72 (s, 1H), 7.23-7.34 (m, 5H), 7.48-7.6 (m, 4H), 7.79 (d, 2H, *J* = 8.00 Hz). ¹³C

NMR (100 MHz, DMSO-*d*₆): δ , ppm 159.95, 145.67, 144.40, 143.56, 137.96, 131.93, 130.54, 129.80, 126.69, 120.60, 120.49, 120.34, 98.59, 58.16, 36.62, 13.05. Anal. Calcd. (%) for C₂₂H₂₁N₅O: C, 71.14; H, 5.70; N, 18.85. Found: C, 71.35; H, 5.75; N, 18.63.

6-amino-4-(4-methoxyphenyl)-3-methyl-1-phenyl-1,4-dihydropyrano[2,3-c]pyrazole-5-carbonitrile (11j)

Colour: White solid. M.p.: 172-174 °C. ¹H NMR (400 MHz, DMSO-*d*₆): δ , ppm 1.79 (s, 3H), 3.75 (s, 3H), 4.63 (s, 1H), 6.91 (d, 1H, *J* = 8.4 Hz), 7.16-7.18 (m, 3H), 7.31 (t, 1H, *J* = 7.2 Hz), 7.38 (t, 1H, *J* = 7.6 Hz), 7.49 (t, 2H, *J* = 7.6 Hz), 7.79 (d, 3H, *J* = 8.4 Hz). Anal. Calcd. (%) for C₂₁H₁₈N₄O₂: C, 70.38; H, 5.06; N, 15.63. Found: C, 69.69; H, 5.85; N, 6.19.

6-amino-4-(3-ethoxy-4-hydroxyphenyl)-3-methyl-1-phenyl-1,4-dihydropyrano[2,3-c]pyrazole-5-carbonitrile (11k)

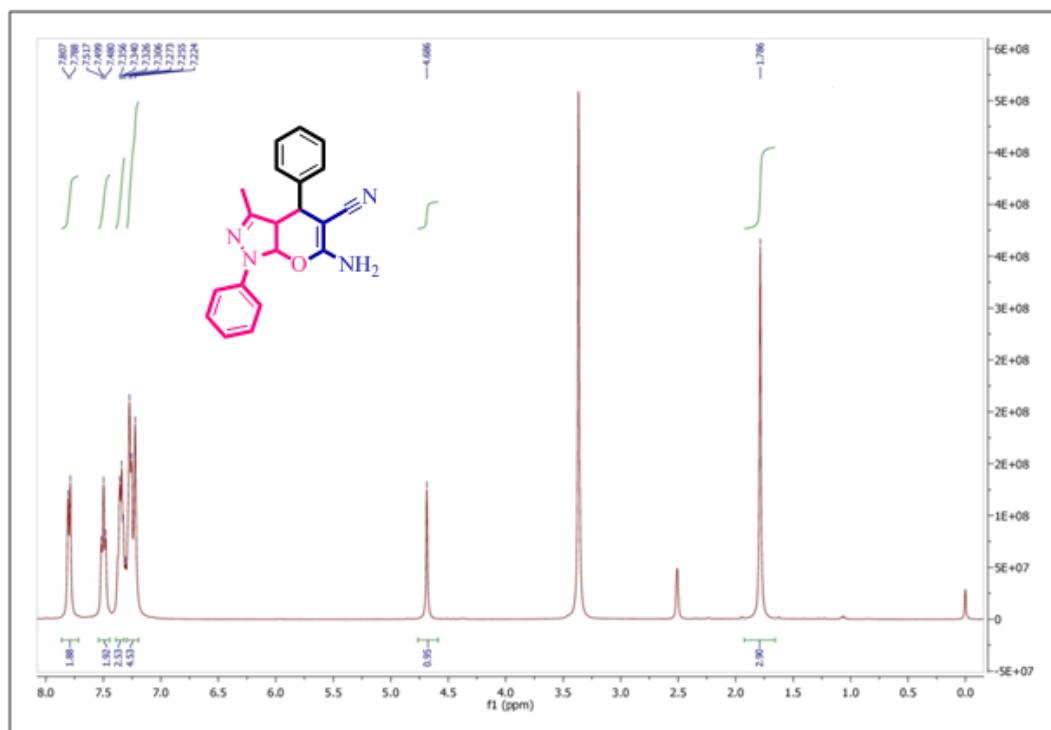

Colour: White solid. M.p.: 167-169 °C. ¹H NMR (400 MHz, DMSO-*d*₆): δ , ppm 1.30 (t, 3H, *J* = 6.8 Hz), 1.82 (s, 3H), 3.96-4.01 (m, 2H), 4.56 (s, 1H), 6.61-7.13 (m, 5H), 7.31 (t, 1H, *J* = 7.2 Hz), 7.49 (t, 2H, *J* = 7.6 Hz) 7.79 (d, 2H, *J* = 8.4 Hz), 8.83 (s, 1H). ¹³C NMR (100 MHz, DMSO-*d*₆): δ , ppm 159.69, 146.91, 146.30, 145.87, 144.23, 138.09, 134.97, 129.79, 126.53, 120.66, 120.57, 120.31, 116.09, 113.96, 99.36, 64.44, 59.15, 36.79, 15.18, 13.13. Anal. Calcd. (%) for C₂₂H₂₀N₄O₃: C, 68.03; H, 5.19; N, 14.42. Found: C, 69.69; H, 5.85; N, 6.19.

6-amino-3-methyl-4-(4-nitrophenyl)-1-phenyl-1,4-dihydropyrazolo[2,3-c]pyrazole-5-carbonitrile (11l)

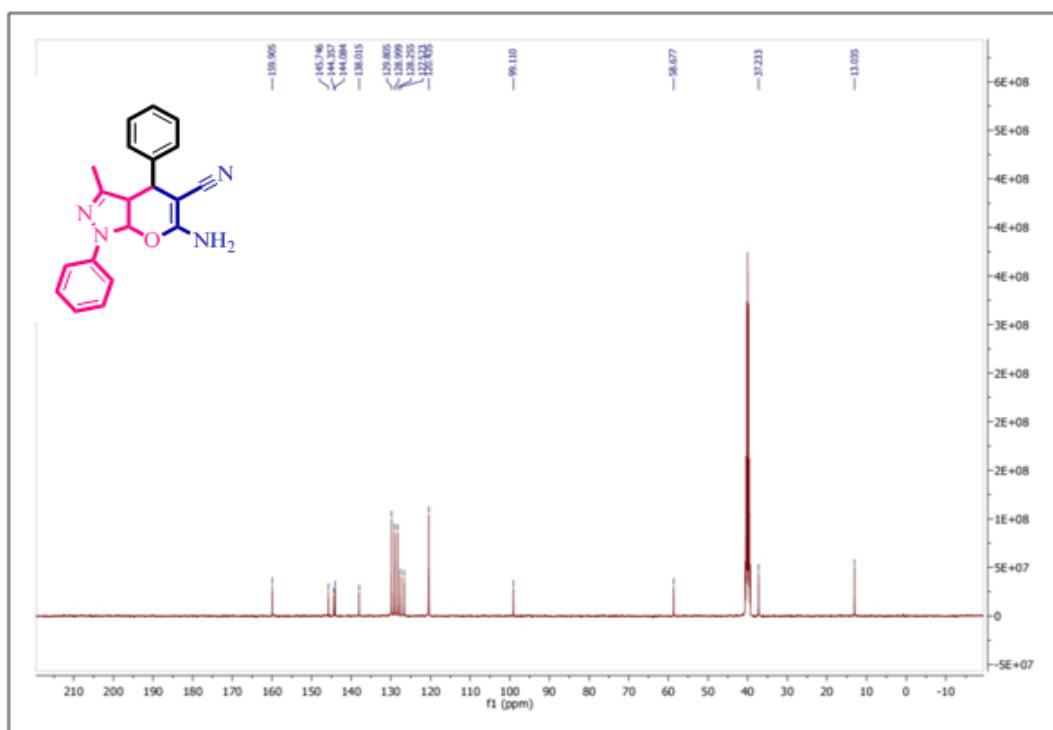

Colour: White solid. M.p.: 191-193 °C. ^1H NMR (400 MHz, $\text{DMSO}-d_6$): δ , ppm 1.82 (s, 3H), 4.94 (s, 1H), 7.44-7.6 (m, 7H), 7.83 (bs, 2H), 8.25 (bs, 2H). ^{13}C NMR (100 MHz, $\text{DMSO}-d_6$): δ , ppm 160.20, 151.66, 147.08, 145.62, 144.48, 137.91, 129.79, 129.68, 126.76, 124.36, 120.54, 120.23, 98.05, 57.38, 36.90, 13.03. Anal. Calcd. (%) for $\text{C}_{20}\text{H}_{15}\text{N}_5\text{O}_3$: C, 64.34; H, 4.05; N, 18.76. Found: C, 64.61; H, 3.97; N, 18.98.

4. Conclusions

We have, for the first time, demonstrated the coordinating behaviour of ANA with metals Co(II), Ni(II), Cu(II), Zn(II), Cd(II) and Pd(II). The ligand and its metal complexes have been characterized by a variety of spectroscopic techniques. The single crystal X-ray structure of ANA and its corresponding Zn(II) complex have shown their ability to form strong as well as weak H-bonding interaction which may have implications in crystal engineering. The related single crystal X-ray structures of Zn(II) complex of 2-aminopyridine and 3-pyridine aldehyde revealed their ability to form 1-dimensional and 2-dimensional structures, respectively. The presence of both aldehyde and amine group helps ANA to have a 3-D structure. Based on spectral data, it was apparent that Pd(II) and Cu(II) complexes show square-planar geometry, whereas Co(II), Ni(II), Zn(II) and Cd(II) complexes showed tetrahedral geometry with $[\text{M}(\text{N})_2(\text{Cl})_2]$ coordination sphere. The ANA acts as mono dentate ligand towards the metal ions through N atom of pyridine ring, orienting the aldehyde and amine potential functional groups of the ligand in the metal complexes. In DFT studies, all the complexes showed excellent nonlinear optical properties. In addition, the biological evaluation results

revealed that Co(II) and Pd(II) complexes have shown significant antimicrobial activity against the tested microorganisms. The scavenging activity of Zn(II) complex showed potent activity with IC_{50} value of $10.14 \pm 2.50 \mu M$ compared to standard ascorbic acid. Zn(II) complex exhibited significant anticancer activity against IMR-32, HepG-2 and Raw 264.7 cell lines compared to cisplatin as the reference control. Furthermore, the molecular docking analysis against EGFR protein receptor, Zn(II) complex showed the lowest binding energy of -5.79 kcal/mol. The molecular docking results strongly correlate with experimental *in vitro* anticancer activity results. In order to extend this work, we have demonstrated the usefulness of a cheaper, low toxic and environmentally benign zinc metal complex, $Zn(ANA)_2Cl_2$ as a catalyst in the to produce a variety of fully substituted pyridines and dihydropyrano[2,3-c]pyrazoles in good yields via MCR approach. The significant advantages of these protocols include readily available substrates, short reaction time, easy workup, and no column chromatographic purification (without any tedious work-up or purification). These advantages made this methodology facile and appropriate to create diverse libraries. The presence of reactive $-CN$ and $-NH_2$ groups at 5 and 6 positions, respectively, renders these compounds ready for further transformations into more complex heterocycles.

CHAPTER-IV

**Synthesis, structural, biological evaluation and DFT studies of Co(II),
Ni(II), Cu(II), Zn(II), Cd(II) and Pd(II) complexes bearing heterocyclic
thiosemicarbazone ligand**

Thiosemicarbazones have an extensive set of N and S donor atoms which have proved their indispensability in coordination chemistry. These ligands are popular due to their great versatility, which is exhibited by their ability to exist in two forms (thione-thiol) and the capacity to bind metal ions in the anionic or neutral form, behaving as monodentate or bidentate ligand [1–6]. These compounds have been explored for their inhibitory action on the DNA enzyme Ribonucleotide diphosphate reductase, as well as their selectivity toward hormone-responsive cancers [7]. Owing to these properties, a number of compounds, both organic and metal-organics, have been derived from thiosemicarbazones and these have many structural and medicinal applications [8]. They have been found to be very active against insects, tuberculosis, influenza, leprosy, bacterial and viral infections, rheumatism, psoriasis, coccidiosis and trypanosomiasis [9–12]. The metal complexes of semicarbazones and thiosemicarbazones have provoked substantial interest because of their industrial and biological importance and many of these compounds have been reported to have expansive spectrum of therapeutic properties [13].

Through decades, metal ions have been continuously establishing themselves in the biological systems and also have proved important to humans in varying levels [14]. Introduction of metal complexes into the biological system can be approved for either therapeutic or diagnostic purposes. Metal ions in the form of complexes enrich their medicinal applications because of their geometrical orientation ascribed chelation ability [15–21].

In the present chapter, we describe the synthesis, characterization and theoretical studies of new heterocyclic appended thiosemicarbazone ligand and their corresponding metal complexes. Further, the new compounds are investigated for their *in vitro* antimicrobial, antioxidant, anticancer, ROS and *in vivo* antidiabetic activities. Interestingly, these complexes exhibit potential biological properties, which are discussed in detail in this chapter.

4.1 Results and discussion

2-aminonicotinaldehyde *N*-methyl thiosemicarbazone (ANMTSC) and its metal complexes are non-hygroscopic and stable under ordinary conditions. Upon heating, the complexes decompose without melting. The ligand is soluble in methanol, ethanol, DMF and DMSO while the complexes are soluble in DMF and DMSO and insoluble in

methanol, ethanol, chloroform, dichloromethane etc. Analytical and molar conductivity data of the complexes are present in Table 4.1. The molar conductance of the complexes (10^{-3} M DMF solution) is in the range of $08\text{-}22 \Omega^{-1}\text{cm}^2\text{mol}^{-1}$ suggesting that metal complexes are non-electrolytes.

Table 4.1 Analytical and molar conductivity data for the ligand and its complexes

| Compound | Elemental analyses: Found (Calculated) | | | | |
|--|--|------------------|----------------|------------------|--|
| | C | N | H | S | Molar Cond. ($\Omega^{-1}\text{cm}^2\text{mol}^{-1}$) |
| $[\text{Co}(\text{ANMTSC})_2(\text{H}_2\text{O})_2]$ | 37.54 (37.57) | 27.33 (27.38) | 4.69 (4.73) | 12.50 (12.54) | 11 |
| $[\text{Ni}(\text{ANMTSC})_2(\text{H}_2\text{O})_2]$ | 37.57 (37.59) | 27.34 (27.40) | 4.69 (4.73) | 12.48 (12.54) | 13 |
| $[\text{Cu}(\text{ANMTSC})_2(\text{H}_2\text{O})_2]$ | 37.19 (37.24) | 27.10 (27.14) | 4.66 (4.69) | 12.39 (12.43) | 18 |

4.1.1 Spectroscopy

The difference between the infrared spectrum of the ANMTSC ligand and its corresponding metal(II) [Co(II), Ni(II), Cu(II), Zn(II), Cd(II) and Pd(II)] complexes have given basic evidence for the coordination mode of the complexes. The IR data of the newly synthesized ligand and its complexes are depicted in Table 4.2 and shown in Fig. 4.1 (a-c). The azomethine ($\text{C}=\text{N}$), thiocarbonyl ($\text{C}=\text{S}$) and $(\text{C}=\text{N})_{(\text{py})}$ groups of the ligand were shown stretching frequencies at 1557 , 1272 and 1582 cm^{-1} , respectively. On

coordination with metal ions, the azomethine and thiocarbonyl stretching frequencies shifted to lower frequencies (1518-1537 and 1227-1250 cm^{-1}) while the (C=N)_(py) stretching frequency remains unchanged, which clearly implies that the ligand coordinates with metal ions through azomethine nitrogen and thiocarbonyl sulphur donor atoms (NS⁻), respectively [22,23]. The IR spectrum of the ligand displayed a band of around 3413, 3315 and 3180 cm^{-1} , which are assigned to pyridine attached NH, terminal NH and thiocarbonyl attached NH groups, respectively. After complexation, stretching frequency of the thiocarbonyl group adjacent to -NH disappeared while the other two bands were unaltered, which strongly pointed to the ligand coordination with all the metal(II) ions in the deprotonated thiol form [24]. The electronic spectral frequencies and magnetic data observed for the complexes [Co(II), Ni(II), Cu(II), Zn(II), Pd(II) and Cd(II)] along with ligand field parameters have been calculated for Co(II) and Ni(II) complexes and the results are represented in Table 4.3. The UV-Visible spectra of the Co(II) complex showed four band frequencies at 8890, 17240, 20000 and 28570 cm^{-1} , respectively, the first three assignable corresponding to ${}^4\text{T}_{1\text{g}}(\text{F}) \rightarrow {}^4\text{T}_{2\text{g}}(\text{F})$ (ϑ_1), ${}^4\text{T}_{1\text{g}}(\text{F}) \rightarrow {}^4\text{A}_{2\text{g}}(\text{F})$ (ϑ_2) and ${}^4\text{T}_{1\text{g}}(\text{F}) \rightarrow {}^4\text{T}_{2\text{g}}(\text{P})$ (ϑ_3) transitions of octahedral geometry [25] and the last band due to charge transfer; this was also further supported by $\vartheta_2 / \vartheta_1$ which lies in the range of 1.80-2.20 for octahedral geometry [26]. The ligand field parameters have been calculated using the equation [27].

$$10 \text{ Dq} = 1/3 (2 \vartheta_2 - \vartheta_3) + 5\text{B}$$

$$\text{B} = \frac{\vartheta_3 + \vartheta_2 - 3 \vartheta_1}{15}$$

The B value was calculated and found to be 705 cm^{-1} . The experimental B value is lower than the free ion value B' [971 cm^{-1} for Co(II)] which gives information about the overlapping of orbitals and d-orbital delocalization. This is in accordance with the observation made by Jorgenson [28], the ligand which coordinate with sulphur donor atom has a low value of B and causes very pronounced nephelauxetic effect. The nephelauxetic effect suggests that the lower the value of β , greater the extent of covalence. For Co(II) complex, β value is less than one indicating the covalent character of the metal-ligand bond. Ni(II) complex reveal bands around 9900, 16390 and 25970 cm^{-1} corresponding to ${}^3\text{A}_{2\text{g}}(\text{F}) \rightarrow {}^3\text{T}_{2\text{g}}(\text{F})$ (ϑ_1), ${}^3\text{A}_{2\text{g}}(\text{F}) \rightarrow {}^3\text{T}_{1\text{g}}(\text{F})$ (ϑ_2) and ${}^3\text{A}_{2\text{g}}(\text{F}) \rightarrow {}^3\text{T}_{1\text{g}}(\text{P})$ (ϑ_3) transitions, respectively, which are characteristic of octahedral geometry [29,30], also further supported by $\vartheta_2 / \vartheta_1$ being equal to 1.66. This value is lower than $\vartheta_2 / \vartheta_1$ value

of 1.80 observed for regular octahedral $[\text{Ni}(\text{H}_2\text{O})_6]^{2+}$ complex. The lowering of value in the present case may be attributed to the asymmetric environment around Ni(II) of the complex. The B value [27] for the complex is 854 cm^{-1} . This value is lower than the free ion value B' [1030 cm^{-1} for Ni(II)] which gives information about the overlapping of orbitals and d-orbital delocalization. However, the Cu(II) complex shows a broad peak at 16000 cm^{-1} , attributed to $^2\text{B}_{1g} \rightarrow ^2\text{A}_{1g}$, $^2\text{B}_{1g} \rightarrow ^2\text{B}_{2g}$ and $^2\text{B}_{1g} \rightarrow ^2\text{E}_g$ transitions, respectively and characteristic of tetragonal or distorted octahedral geometry [31-34] and these bands overlap to give one broad absorption peak in the spectrum of Cu(II) complex [35]. The Pd(II) complex show three peaks at 16850 cm^{-1} ($^1\text{A}_{1g} \rightarrow ^1\text{A}_{2g}$), 20400 cm^{-1} ($^1\text{A}_{1g} \rightarrow ^1\text{B}_{1g}$) and 24350 cm^{-1} ($^1\text{A}_{1g} \rightarrow ^1\text{E}_g$), these transitions being characteristic of square-planar geometry [23]. The electronic spectra of Zn(II) and Cd(II) complexes do not show any $d \rightarrow d$ transition, which may be due to d^{10} electronic configuration [36]. It has been reported that tetrahedral is the most favoured one and it is confirmed from analytical data [37].

The Co(II) and Ni(II) complexes exhibited magnetic moment values of 4.98 B.M. and 3.28 B.M. which might be attributed to the octahedral geometries around Co(II) [38] and Ni(II) [26]. The Cu(II) complex showed a magnetic moment of 1.81 B.M. This value is close to spin-only value with a slight allowance for a magnetic moment from spin-orbit coupling, suggesting tetragonal geometry around Cu(II) [39,40]. Zn(II), Pd(II) and Cd(II) complexes are diamagnetic in nature [41].

ESR spectroscopy was performed to determine the existence of unpaired electrons. In the present study, ESR spectrum of Cu(II) complex was performed at room temperature in solid state and the recorded spectrum is shown in Fig. 4.2 and the ESR parameters are represented in Table 4.4. From the spectral data, the g values obtained for Cu(II) complex indicates that $g_{\parallel} (2.25) > g_{\perp} (2.06) > 2.0023$, and so the unpaired electron lies predominantly in $d_{x^2-y^2}$ orbital, a characteristic feature of tetragonal or distorted octahedral geometry [42].

From the axial spectra, the g-values were connected with exchange interaction coupling constant (G). The nature of the ligand was also determined using the following expression

$$G = \frac{g_{\parallel} - 2.0023}{g_{\perp} - 2.0023}$$

As reported by Karlin and Zubieta (Eds.) [43], if $G > 4$, the exchange interaction was insignificant due to local tetragonal axes that were aligned parallel. If $G < 4$, the exchange interaction was reasonable and the local tetragonal axes were misaligned. The G value (4.29) observed for Cu(II) complex was found to be more than four, indicating that there was no exchange interaction in solid state as suggested.

A_{\parallel} - The parallel component of copper hyperfine splitting has also been obtained for the complex from its well resolved g_{\parallel} components and values are given in Table 3.9. It was assumed that Cu(II) free ion spin-orbit coupling constant, $\lambda_0 = -828 \text{ cm}^{-1}$, the orbital reduction parameters, K^2_{\parallel} and K^2_{\perp} have been calculated by correlating electronic and ESR spectral data by the following expression [44,45].

$$g_{\parallel} = 2.0023 - \frac{8 K^2_{\parallel} \lambda_0}{\Delta E(2\text{B}1\text{g} \rightarrow 2\text{B}2\text{g})}$$

$$g_{\perp} = 2.0023 - \frac{2 K^2_{\perp} \lambda_0}{\Delta E(2\text{B}1\text{g} \rightarrow 2\text{B}2\text{g})}$$

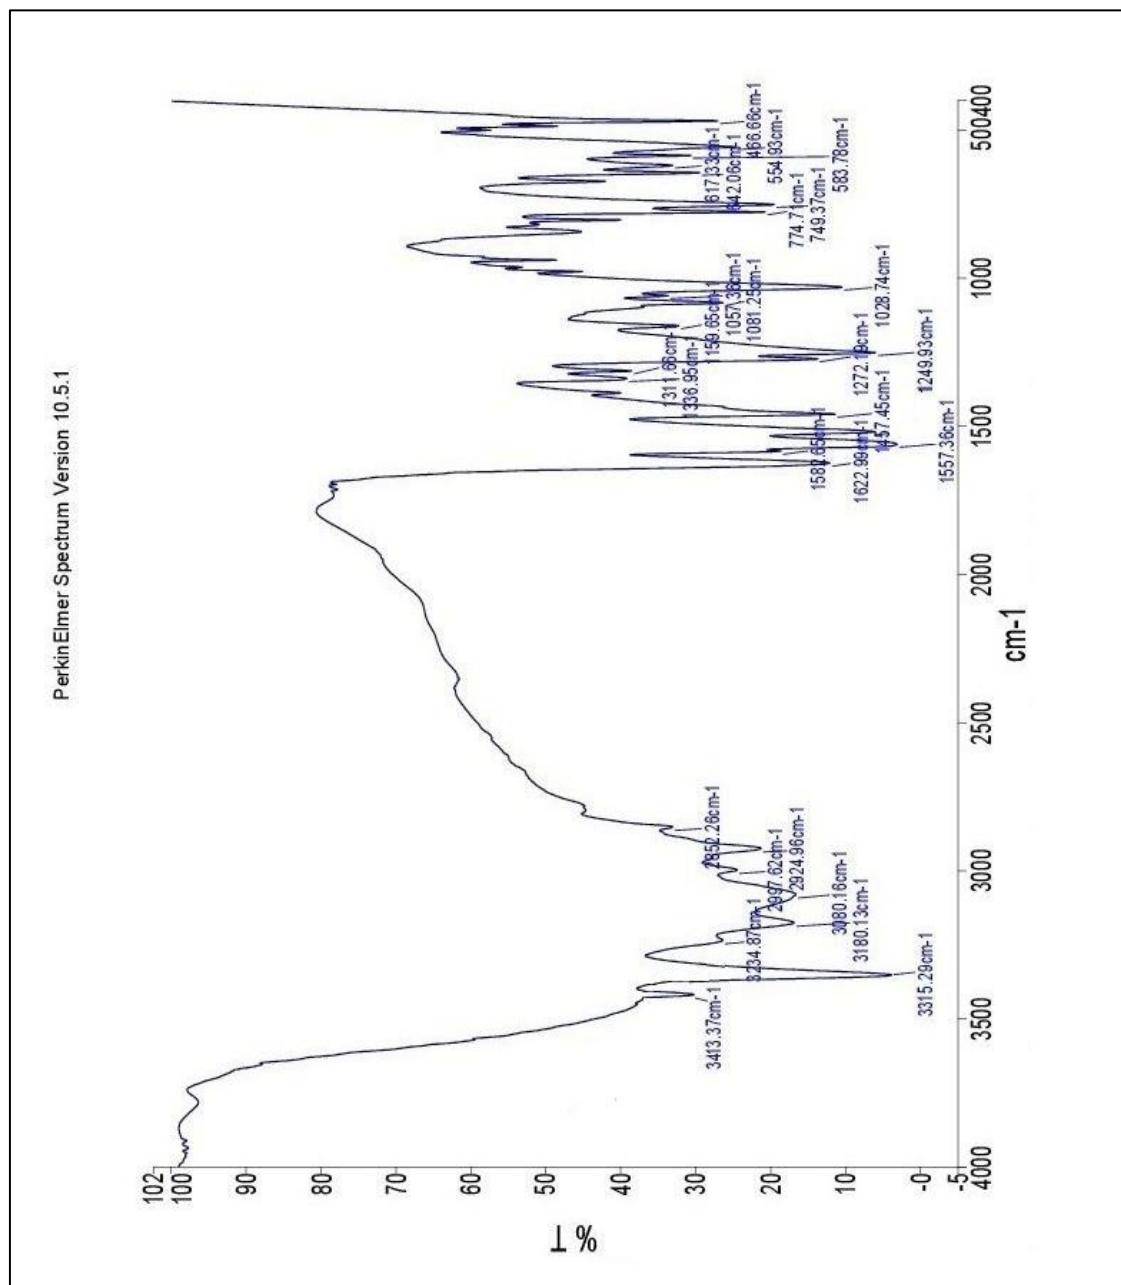

Hathaway and Billing [46,47] have pointed out that $K^2_{\parallel} < K^2_{\perp}$ for in-plane pi-bonding and $K^2_{\parallel} > K^2_{\perp}$ out of plane pi-bonding, in the present case while the observed value is $K^2_{\parallel} > K^2_{\perp}$, which implies that the present complex was supposed to be out of plane pi-bonded. Further, the spin-orbit coupling constant also has been evaluated using the equation,

$$g_{\parallel} = 2.0023 - \frac{8\lambda}{\Delta E}$$

From the results, the λ value for Cu(II) complex (-495 cm^{-1}) is lower than free ion value suggesting the significant mixing of the ground and excited terms.

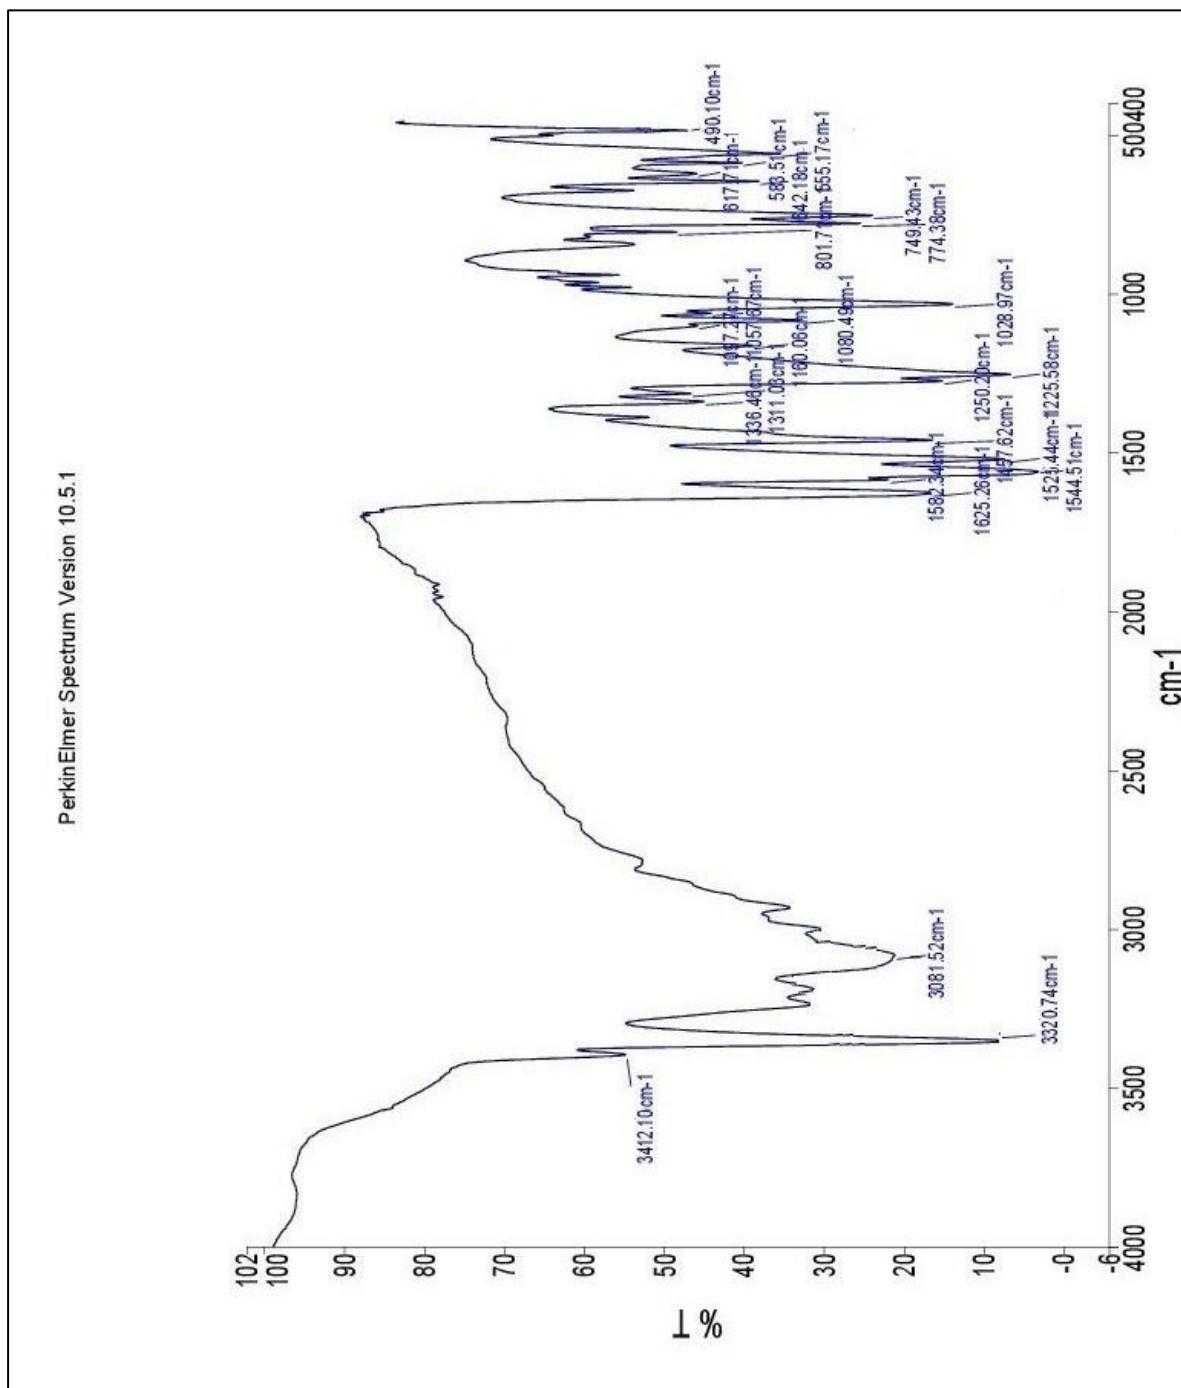

In ^1H NMR spectra of the ligand, the thiocarbonyl attached N–H and terminal N–H protons showed signals of around 11.23 and 8.38 ppm, respectively. In the complexes [Zn(II), Pd(II) and Cd(II)] thiocarbonyl attached N–H proton signals disappeared, which clearly indicates coordination of the ligand in the anionic form after deprotonation and the terminal N–H proton appeared at 8.19–8.43 ppm. The signal azomethine CH proton appeared at 8.15 ppm and the same proton occurred in the complexes around 7.93–8.20 ppm. The signals due to the protons of NH_2 attached to the pyridine ring were observed at 6.98 ppm as the singlet, whereas, in the complexes, NH_2 appeared in the region at 6.97–7.02 ppm. The aromatic protons of ligand and complexes

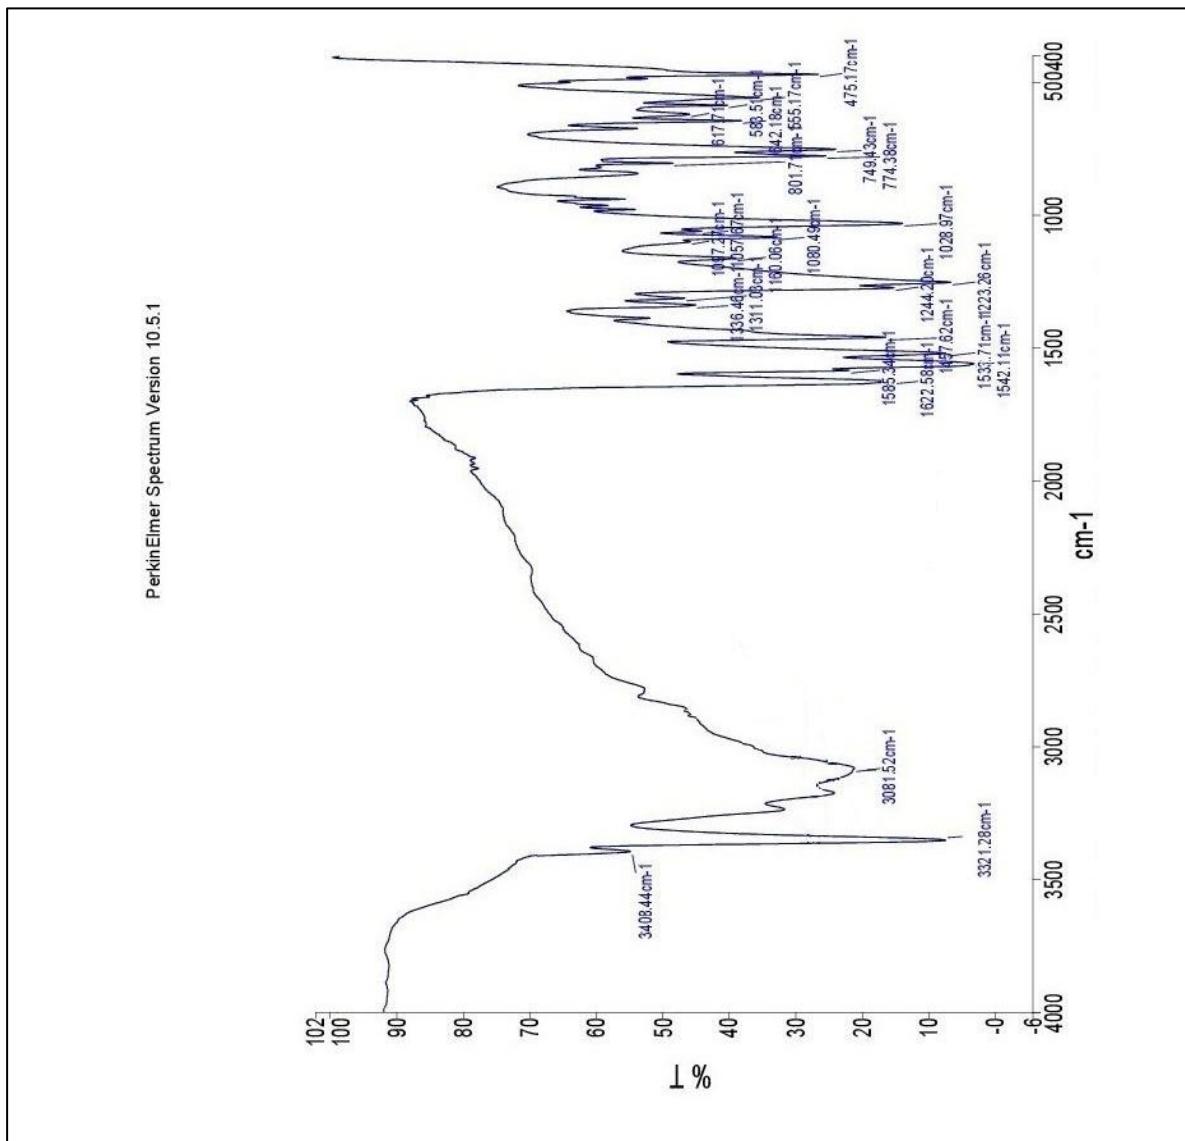

(pyridine ring and terminal phenyl) appeared in the range of 8.05-6.55 ppm. ^{13}C NMR spectrum of the ligand displayed resonances due to C=S and C=N carbons at 177.5 and 156.6 ppm, respectively. Conversely, in the spectra of Zn(II), Pd(II) and Cd(II) complexes, C=S, and C=N chemical shifts appeared around 178.7-175.2 ppm and 147.2–141.1 ppm, respectively. Chemical shift of all other protons and carbons was observed in the expected regions as shown Fig.s 4.3-4.6.

4.1.2 X-ray analysis

X-ray analysis of single crystal of ANMTSC compound under investigation showed that it belongs to monoclinic crystal system, with space group $P2_1/n$ having four molecules per unit cell (i.e. $Z = 4$). The dimensions of the unit cell are $a = 6.1537(3)$ Å, $b = 22.0194(12)$ Å, $c = 7.2700(4)$ Å, $\alpha = 90^\circ$, $\beta = 92.149(2)^\circ$, $\gamma = 90^\circ$, with volume $V = 984.40(9)$ Å³, at temperature $T = 296(2)$ K, calculated density D being 1.412 g cm⁻³ ($M = 223.3$ g mol⁻¹), with absorption coefficient μ , for Mo K_α line, as 0.296 mm⁻¹. Refinement of full-matrix least-squares method on F^2 converged with goodness-of-fit 1.175. R indices (all data) has come out to be $R1 = 0.0633$ and $wR2 = 0.1493$. Final R indices [$I > 2$ sigma (I)] are $R1 = 0.0592$ and $wR2 = 0.1467$.

A view of ANMTSC showing atom-labeling scheme appears in Fig. 4.7. Experimental molecular structure parameters comprising crystal data, bond lengths, bond angles, dihedral angles and intra-molecular hydrogen bond are presented in Tables 4.5-4.6. The crystal data for ANMTSC is available as supplementary material from CCDC (Cambridge Crystallographic Data Centre) 1576355, free of charge, at www.ccdc.cam.ac.uk/centre/retrieving.html (or CCDC, 12 Union Road, Cambridge CB2 1EZ, UK; fax: 44(0) 1223336033; email: deposit@ccdc.com.ac.uk)

4.2 DFT computations

4.2.1 Molecular geometry

Obtaining the optimized structures with minimum energy is the initial prerequisite for carrying out computations to determine the characteristics of any molecule. So, the complexes under investigation were subjected to meticulous conformational study around free rotation bonds. The optimized structures corresponding to minimum on the potential energy surface were determined for each of the six complexes by solving self-consistent field equation iteratively. On geometry optimization, the global minimum energy was

found to be -2264.12440 Hartree, -2289.27901 Hartree, -2315.681002 Hartree, -2191.94083 Hartree, -2132.55260 Hartree and -2092.658898 Hartree, respectively for Co(II), Ni(II), Cu(II), Zn(II), Cd(II) and Pd(II) complexes, respectively. The optimized structures of these complexes are shown in Fig. 4.8 along with the numbering of atoms and the geometrical parameters like bond lengths and bond angles are given in Table 4.7.

Based on the results of DFT computations, all the complexes assume C1 point group symmetry. Each of the Co(II), Ni(II) and Cu(II) complexes consists of 55 atoms and 159 fundamental vibrations are observed. Zn(II), Cd(II) and Pd(II) complexes consist of 49 atoms each and 141 fundamental vibrations are observed. All the vibrations of C1 point group symmetry belong to a species which are active in both infrared absorption and Raman scattering.

4.2.2 Frontier molecular orbitals

The Co(II), Ni(II), Cu(II), Zn(II), Cd(II) and Pd(II) complexes were thought to have frontier orbitals which are simply HOMO and LUMO. These frontier molecular orbitals are considered when evaluating the kinetic characteristics of reactants and reactions. At distances greater than typical bond lengths, the maximum orbital overlap is between frontier molecular orbitals, which are likely to be the main initial interactions as reactants approach. They were used to find frontier electron density for predicting the most probable reactive position in π -electron systems. The gap between HOMO and LUMO exemplifies the chemical stability of a molecule. A small gap designates significant degree of intermolecular charge transfer from electron-donor groups to efficient electron-accepter groups through π -conjugated path [48].

The energies of HOMO, LUMO and frontier molecular orbital gap at DFT/B3LYP/SDD level of theory for complexes are depicted in Fig. 4.9. The frontier molecular orbital parameters of the compounds are presented in Table 4.8. The frontier molecular orbital energy gap of Co(II), Ni(II), Cu(II), Zn(II), Cd(II) and Pd(II) complexes were evaluated as 1.28926, 1.52708, 0.75674, 1.95565, 2.12083 and 0.14748 eV, respectively. It can be noticed that the frontier molecular orbital gap is small and hence, the complexes under investigation are more stable and polarizable. From the results, the frontier orbitals energy gap is found to be in the order Cd(II) > Zn(II) > Ni(II) > Co(II) > Cu(II) > Pd(II). The same order is followed for determining chemical potential (μ) values for the complexes. Based on the frontier orbital energies and chemical potential values, the Cd(II) complex has greater chemical reactivity and chemical stability, whereas Pd(II) complex has lower chemical reactivity and chemical stability.

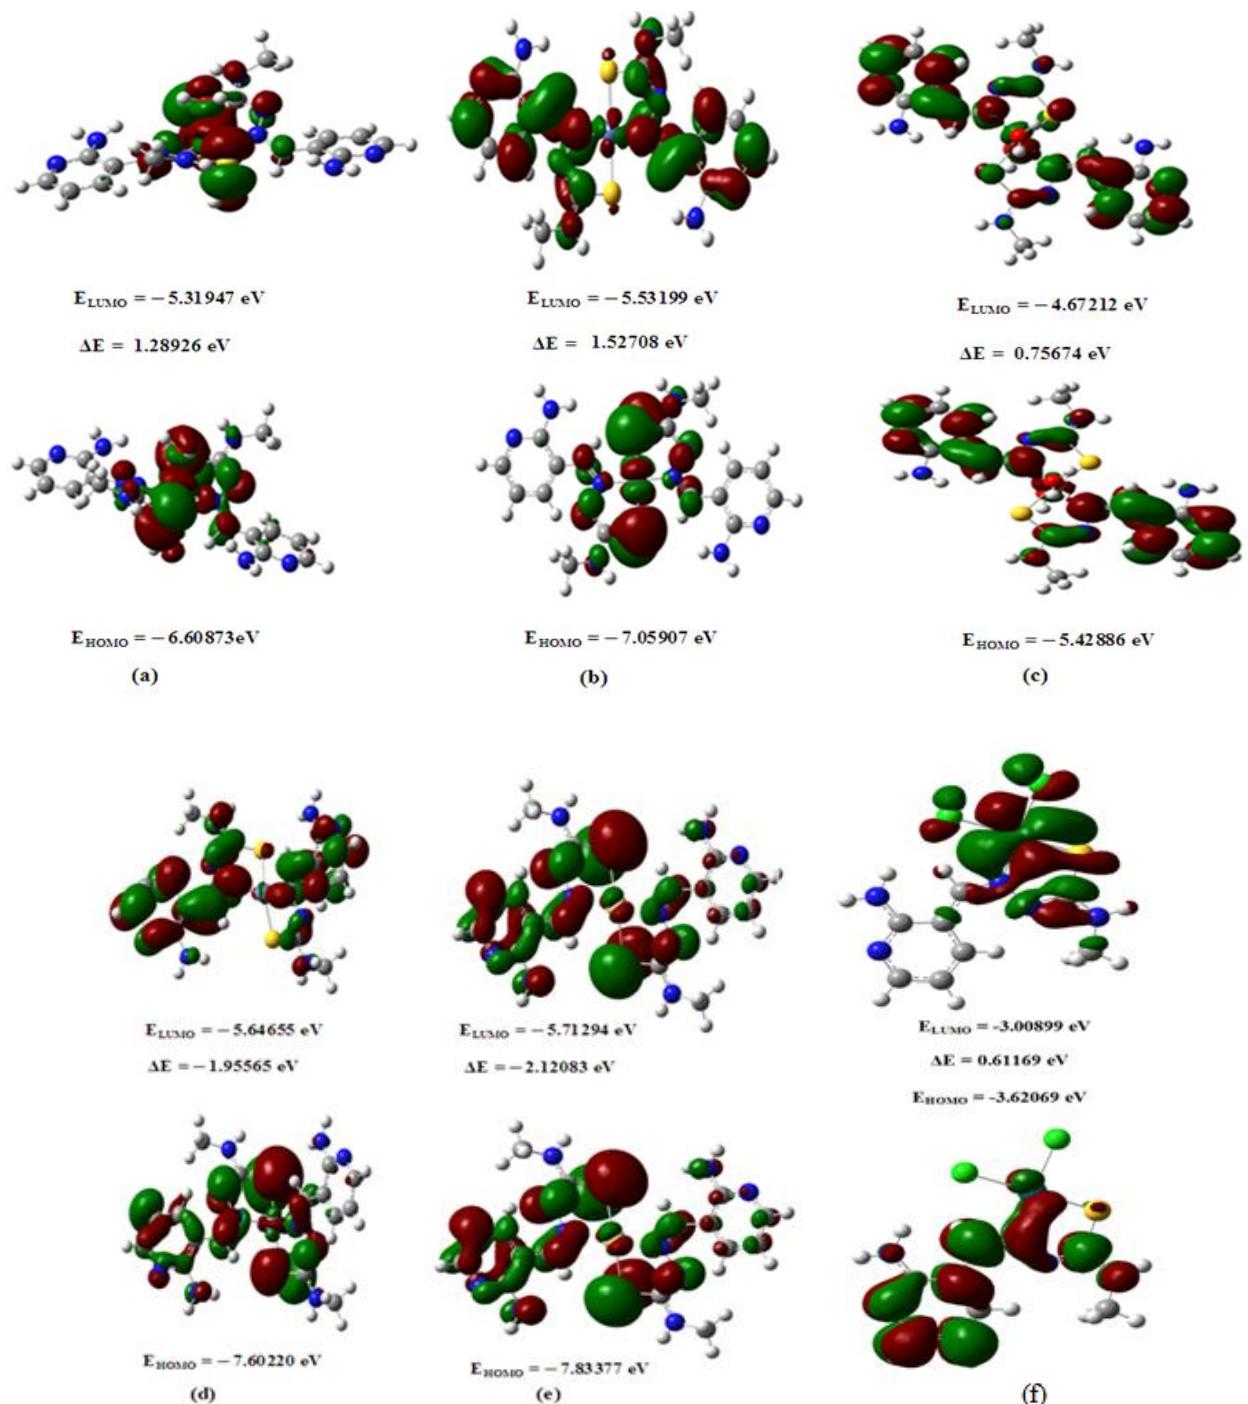

Fig. 4.9 Frontier molecular orbitals of (a) Co(II), (b) Ni(II), (c) Cu(II), (d) Zn(II), (e) Cd(II) and (f) Pd(II) metal complexes.

4.3 Biological evaluations

4.3.1 *In vitro* antimicrobial activity

The antimicrobial activity of the newly synthesized ligand and its metal complexes were evaluated against certain human sensitive pathogenic two gram-positive and two gram-negative bacteria (*Staphylococcus aureus*, *Bacillus subtilis*, *Escherichia coli* and *Klebsiella pneumoniae*) and two fungal strains (*Penicillium notatum* and *Aspergillus niger*) by disc diffusion method. The antimicrobial activity results of the synthesized compounds as well as standard drugs are summarized in Tables 4.9 and 4.10. From the results, it was observed that the ligand does not show any activity against tested microorganisms. In all the cases the activity of complexes increases with increasing concentration of the test samples and standards ^[69]. In our investigation, it was observed that Cd(II) complex showed excellent antibacterial activity against the tested strains *S. aureus* (MIC: 1.562 μ g/mL), *B. subtilis* (MIC: 3.125 μ g/mL), *K. pneumoniae* (MIC: 3.125 μ g/mL) and *E. coli* (MIC: 1.562 μ g/mL), respectively and the Cu(II) complex displayed good activity against *S. aureus* (MIC: 6.25 μ g/mL), *B. subtilis* (MIC: 12.5 μ g/mL) and *E. coli* (MIC: 6.25 μ g/mL) compared to streptomycin standard drug. Complexes Ni(II) and

Pd(II) exhibited moderate activity against *S. aureus* and *K. pneumoniae* with MIC values of 12.5 $\mu\text{g/mL}$ and 6.25 $\mu\text{g/mL}$, respectively. In the antifungal activity, the Cd(II) complex showed excellent activity against *P. notatum* compared to standard drug with MIC value of 3.125 $\mu\text{g/mL}$. The complexes Ni(II) and Cd(II) showed potent activity against *A. niger* with MIC values of 6.25 and 6.25 $\mu\text{g/mL}$, respectively. However, the other complexes showed poor activity against the tested microorganisms.

Table 4.9 MIC values of antibacterial activity of the compounds ($\mu\text{g/mL}$)

| Compound | <i>S. aureus</i> | <i>B. subtilis</i> | <i>K. pneumoniae</i> | <i>E. coli</i> |
|--------------|------------------|--------------------|----------------------|----------------|

4.3.2 *In vitro* antioxidant property

The scavenging activity of the ligand and its metal complexes were extensively studied by DPPH (1,1-Diphenyl-2-picryl-hydrazyl) method [49] and the values are indicated in terms of IC_{50} . DPPH is an established radical and is utilized to scavenge other radicals. DPPH radical shows deep violet colour in solution and has strong absorption at 517 nm. When the DPPH radical is paired off with the free radical scavenger, the colour of the solution vanishes. DPPH becomes colourless or pale yellow when neutralized and the resulting decolorization corresponds to the number of electrons paired up. From Fig. 4.10 and Table 4.11 which represents the IC_{50} values of the newly synthesized compounds, it is clear that these synthesized compounds showed impressive scavenging activity compared to ascorbic acid (standard). Importantly, Co(II) and Zn(II) complexes exhibited the most potent scavenging activity with IC_{50} values of $11.17 \pm 1.92 \mu\text{M}$ and $10.79 \pm 0.85 \mu\text{M}$, respectively and also Ni(II) and Pd(II) complexes showed moderate scavenging ability with IC_{50} values of $18.43 \pm 1.30 \mu\text{M}$ and $20.31 \pm 1.92 \mu\text{M}$ compared to standard drug ascorbic acid. The other complexes Cu(II) and Cd(II) exhibited poor antioxidant activity with IC_{50} values of $34.96 \pm 1.82 \mu\text{M}$ and $26.08 \pm 1.03 \mu\text{M}$, respectively and ANMTSC ligand showed least ($IC_{50} = 38.79 \pm 1.03 \mu\text{M}$) activity. Based on IC_{50} values the order of activity is Zn > Co(II) > Ni(II) > Pd(II) > Cd(II) > Cu(II) > ANMTSC.

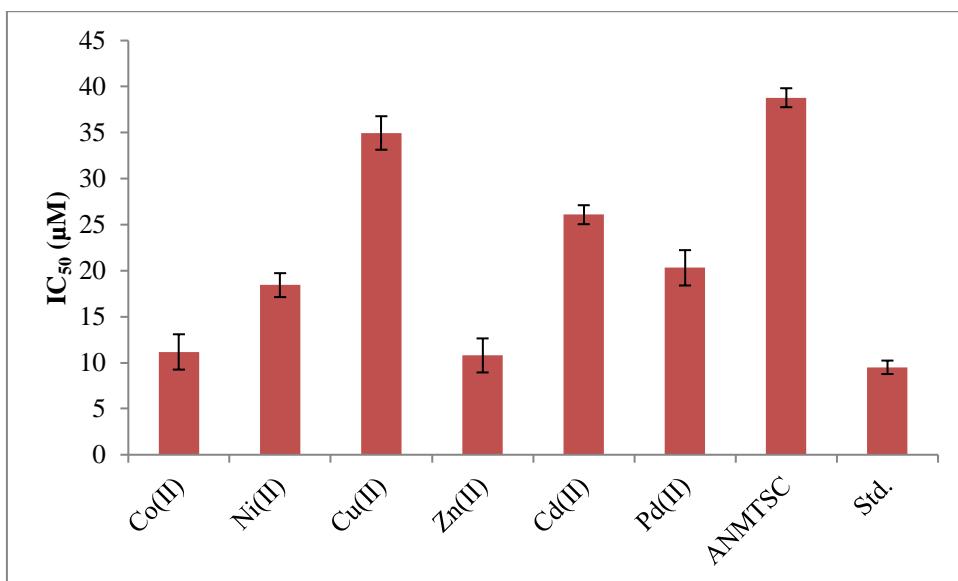

Fig. 4.10 Antioxidant activity of ANMTSC and its metal complexes.

Table 4.11 IC₅₀ values of DPPH scavenging activity of ligand ANMTSC and its complexes

| Compound | IC ₅₀ (μM) |
|---------------|-----------------------|
| Co(II) | 11.17 ± 1.92 |
| Ni(II) | 18.43 ± 1.30 |
| Cu(II) | 34.96 ± 1.82 |
| Zn(II) | 10.79 ± 0.85 |
| Cd(II) | 26.08 ± 1.03 |
| Pd(II) | 20.31 ± 1.92 |
| ANMTSC | 38.79 ± 1.03 |
| Ascorbic acid | 9.50 ± 0.73 |

4.3.3 *In vivo* blood glucose level test

In vivo blood glucose level test has been carried out to screen antidiabetic property of the compounds. Diabetes induced rats were divided into nine (group II-X) groups and each group consisted of six rats other than group I and group II. These two were employed as normal control and diabetic control, group III had metformin as standard and the groups IV-X were employed as test groups. The standard and the prepared compounds were served orally at 20 mg/kg. After treatment, blood samples were taken from all the groups on 1st day, 7th day and 14th day and then blood glucose levels were recorded by using glucometer. The antidiabetic activity of the test compounds are shown in Fig. 4.11 and blood glucose test results are summarized in Table 4.12, where one can see that compared to the standard drug Metformin, Zn(II) and Pd(II) complexes showed good antidiabetic activity compared to other complexes and free ligand.

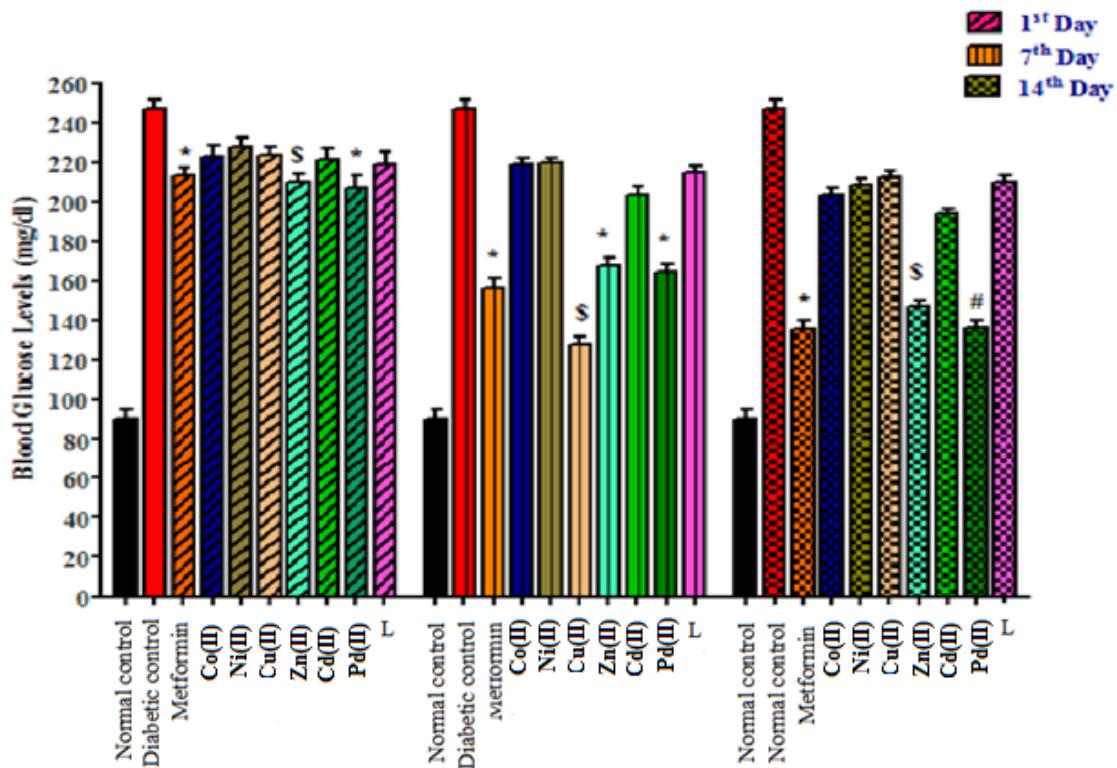

Fig. 4.11 Antidiabetic activity of the ANMTSC and its metal complexes (20 mg/Kg).

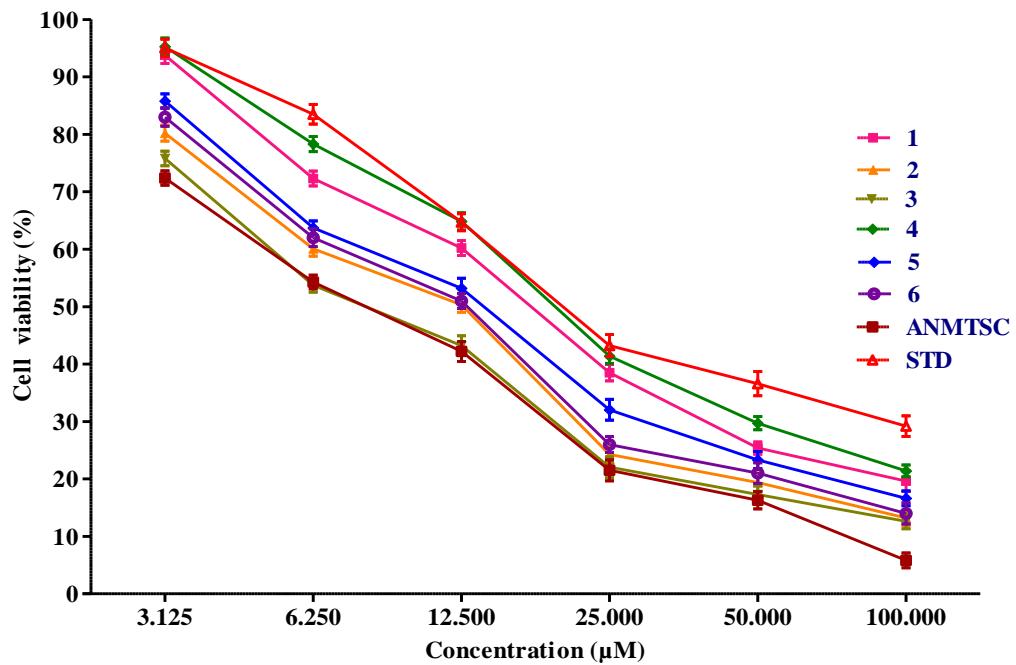

Table 4.12 Effect of prepared compounds on fasting blood glucose levels in alloxan induced diabetic rats in sub acute study (14 days study)

| Group | Dose (mg/kg b.w.) | Fasting blood glucose level (mg/dl) | | |
|-------|--------------------|-------------------------------------|---------------------|----------------------|
| | | 1 st Day | 7 th Day | 14 th Day |
| I | Normal control | 90.70 ± 4.62 | 90.70 ± 4.83 | 90.70 ± 4.52 |
| II | Diabetic control | 246.00 ± 5.37 | 246.00 ± 5.37 | 246.00 ± 5.37 |
| III | Metformin 20 mg/Kg | 213.26 ± 4.27 | 156.53 ± 4.62 | 135.93 ± 4.20 |
| IV | Co(II) 20 mg/Kg | 223.00 ± 5.14 | 219.20 ± 3.28 | 203.47 ± 3.25 |
| V | Ni(II) 20 mg/Kg | 227.41 ± 4.68 | 219.30 ± 3.19 | 208.50 ± 3.29 |
| VI | Cu(II) 20 mg/Kg | 223.96 ± 6.61 | 217.83 ± 4.38 | 212.36 ± 3.27 |

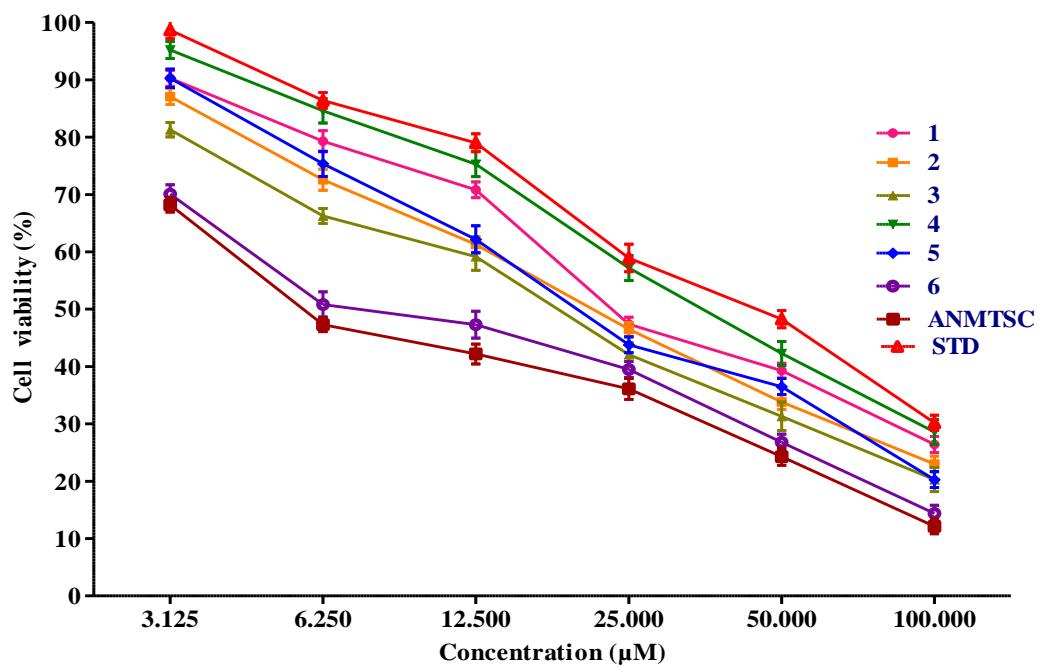

| | | | | |
|------|-----------------|---------------|---------------|---------------|
| VII | Zn(II) 20 mg/Kg | 210.41 ± 4.03 | 168.20 ± 4.29 | 147.40 ± 3.50 |
| VIII | Cd(II) 20 mg/Kg | 221.51 ± 5.59 | 204.10 ± 3.40 | 194.30 ± 2.10 |

| X | ANMTSC 20 mg/Kg | 219.00 ± 6.50 | 214.83 ± 3.20 | 210.36 ± 3.20 |

4.3.4 *In vitro* cytotoxicity

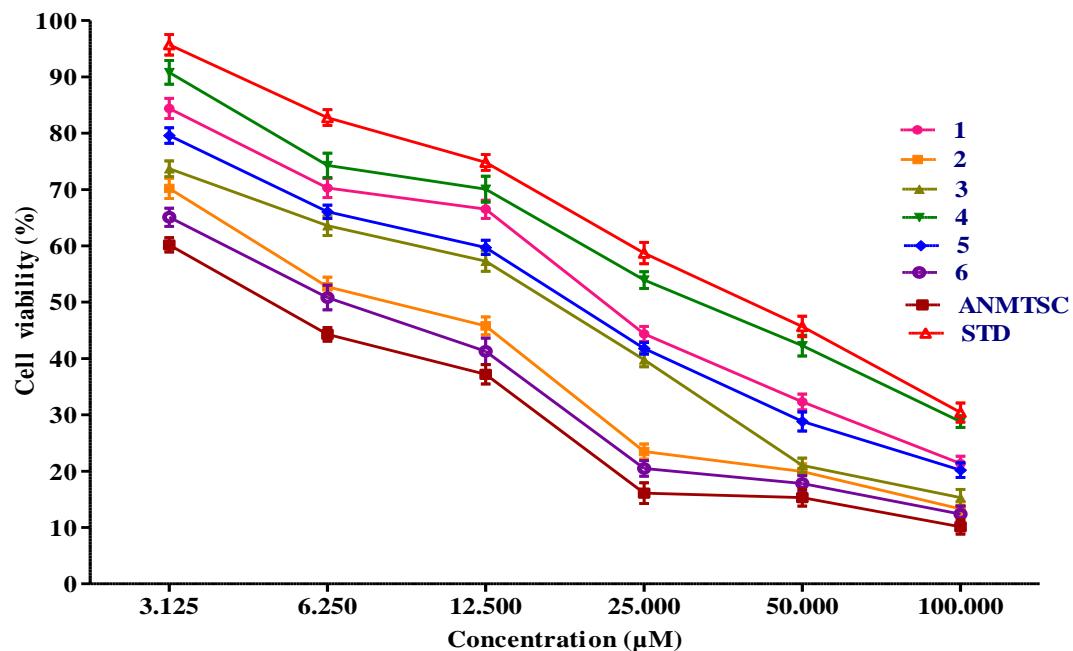

To explore the cytotoxic effects of the synthesized compounds, an MTT assay was carried out by using cisplatin as a reference drug. As shown in Fig. 4.12 survival curves have been drawn for MCF-7, HeLa, A549 and IMR-32 cancer cell lines. IC₅₀ values of the tested compounds are summarized in Table 4.13. All the compounds have shown potent to moderate activity against all the tested cell lines when compared to the standard drug. The results showed that Co(II) and Zn(II) complexes displayed most potential cytotoxic property against four panel cell lines with IC₅₀ values of 15.27 ± 0.10 μM and 10.28 ± 0.69 μM against HeLa; 9.91 ± 0.37 μM and 9.80. ± 0.83 μM against MCF-7; 12.57 ± 0.36 μM and 11.08 ± 0.57 μM against A549, and 13.92 ± 0.58 μM and 10.41 ± 0.60 μM against IMR-32, respectively. Besides, the Cd(II) complex showed moderate activity against HeLa and IMR-32 with IC₅₀ values of 20.15 ± 0.69 μM and 22.78 ± 0.25 μM, respectively. The remaining compounds exhibited reasonable cytotoxic property with the IC₅₀ values ranging from 30.23 ± 0.18 μM to 48.20 ± 0.91 μM for the four cell lines.

4.3.5 Reactive oxygen species (ROS)

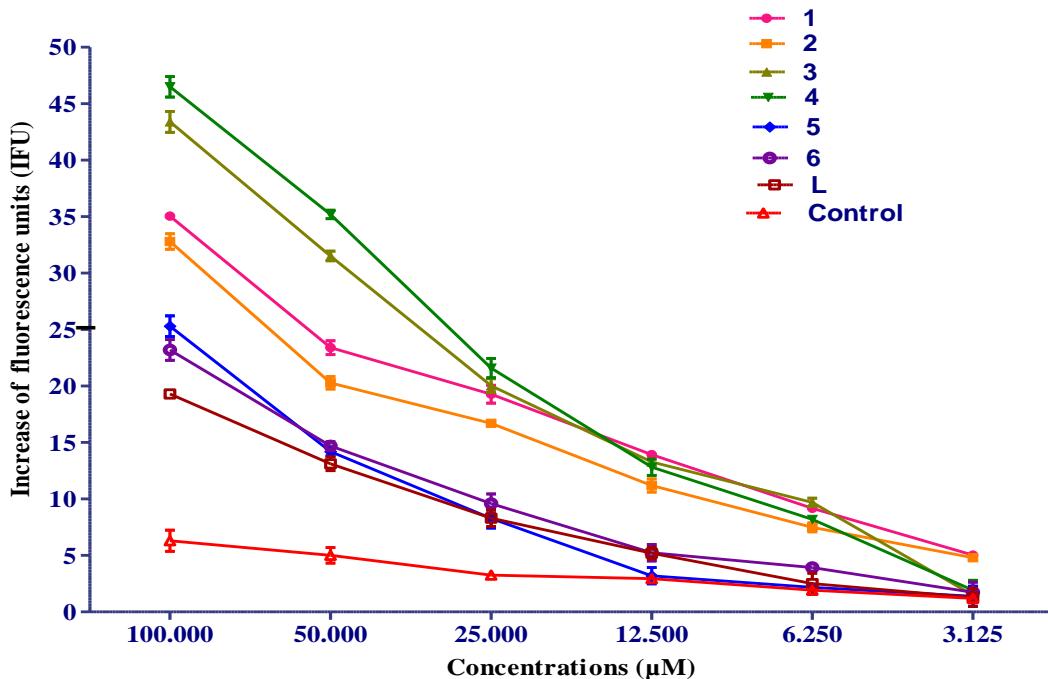

ROS has a predominant role in cell death through cellular senescence paving because of which there is a demand for therapeutic drugs that may prevent oxidative stress induced neuro degeneration. It was highly possible that the pro-oxidant effect is responsible for the apoptotic activity of these extracts. ROS has key signaling molecules to modulate cell death [50]. Accumulating evidence indicates that when high levels of ROS were produced by cancer injected cells, it led to a state of increased basal oxidative stress. The increased production of ROS in cancer cells was observed in *in vitro* studies [51]. Ahmad et al. demonstrated that naringenin leads to cell death in cancer cells *via* inducing ROS generation [52]. We therefore investigated the effectiveness of methanolic extract in generation of ROS. It was found that exposure of all four cancer cells to these extracts dramatically enhanced generation of intracellular ROS at different levels in a dose dependent manner in all cell lines. The results of ROS generation effect of methanolic extract on cancer cell lines HeLa, MCF-7, A549 and IMR-32 are shown in Fig. 4.13. The results showed that the methanolic extract significantly increased the ROS production in all the cell cultures.

[1 = Co(II), 2 = Ni(II), 3 = Cu(II), 4 = Zn(II), 5 = Cd(II), 6 = Pd(II) complexes and L = ANMTSC].

4.4 *In silico* molecular docking studies

The *in silico* molecular docking analysis of the ligand and its metal complexes against epidermal growth factor (EGFR) was carried out to verify the relation between *in vitro* anticancer activity results and binding affinities of the inhibitors by using AutoDock programme. Docking results revealed that ligand and its metal complexes were strongly bound to the receptors of EGFR protein by exhibiting the best ligand pose binding energy values i.e., -3.97 (ANMTSC), -5.91 [Co(II)], -5.19 [Ni(II)], -4.51 [Cu(II)], -6.81 [Zn(II)], -5.75 [Cd(II)] and -5.80 [Pd(II)] kcal/mol, respectively. The efficient interactions of the complexes with the protein when compared with free ligand with protein may be due to their orientation in the grid of the protein. The *in silico* molecular docking studies of the ligand and its complexes showed that all synthesized compounds interact with amino acid residues of the EGFR protein receptor by forming hydrogen bonds. Among all the complexes, Zn(II) complex showed the lowest binding energy (-6.81 kcal/mol) with EGFR protein receptor. Five hydrogen bonds were observed between Zn(II) complex and EGFR protein receptor. Two hydrogen bonds were formed with residue ARG817 with bond distances of 2.33 Å and 2.10 Å, while the remaining three hydrogen bonds with LYS851, ASN818 and ASP831 residues had bond distances of 1.99 Å, 2.22 Å and 1.79 Å, respectively. Along with these hydrogen bonds, there was a hydrophobic interaction with ARG817. When compared with ligand the other complexes Co(II), NI(II), Cu(II), Cd(II) and Pd(II) exhibited good binding energies with EGFR protein receptor. The binding energies, number of hydrogen bond(s), their bond lengths and residues responsible for the hydrogen bonds are shown in Table 4.14. The best confirmation of ligand and complexes were visualized and shown in Fig. 4.14. In conclusion, the docking results strongly support the *in vitro* anticancer activity results.

4.5 Conclusions

The present chapter dealt with synthesis and characterization of new ANMTSC ligand and its corresponding Co(II), Ni(II), Cu(II), Zn(II), Cd(II) and Pd(II) complexes. The molecular structure of the ligand was determined by XRD. The ligand acts as monobasic, bidentate coordination towards metal ion and coordinates through imine nitrogen and thiocarbonyl sulphur atoms, which was confirmed by various spectroscopic tools. Based on Spectral data and theoretical studies Co(II) and Ni(II) complexes have octahedral geometry, Cu(II), Pd(II) complexes have distorted octahedral, square-planar and while the complexes Zn(II) and Cd(II) are tetrahedral geometry. The ESR parameters of the Cu(II) complex confirm that the metal-ligand bonds are covalent out of plane pi-bonds. In biological applications, Co(II) and Zn(II) complexes were found to be most potent antioxidant agents with IC₅₀ values of 11.17 ± 1.92 μM and 10.79 ± 1.85 μM, compared to the reference drug ascorbic acid as well as Co(II) and Zn(II) complexes displayed excellent anticancer activity with IC₅₀ values of 15.27 ± 0.10 μM, 10.28 ± 0.69 μM (for HeLa), 9.91 ± 0.37 μM, 9.80 ± 0.83 μM (for MCF-7), 12.57 ± 0.36 μM, 11.08 ± 0.57 μM (for A549) and 13.92 ± 0.58 μM, 10.41 ± 0.60 μM (for IMR-32) cell lines. The Cu(II) and Zn(II) complexes showed notable reduction in blood glucose level. Furthermore, the Cd(II) complex exhibited excellent antibacterial activity against two gram positive and two gram negative bacteria such as *B. subtilis*, *S. aureus*, *K. pneumoniae* and *E. coli*. The Ni(II) and Cd(II) complexes exhibited most promising

antifungal activity. In future, these encouraging results would prove useful in designing and developing new drugs that combat cancer.

CHAPTER-V

**Complexation of 2-aminonicotinaldehyde benzoxazinonyl acetic acid hydrazone with Co(II), Ni(II), Cu(II), Zn(II), Cd(II) and Pd(II) ions:
Synthesis, structural investigation, DFT and biological evaluations**

Hydrazones are azomethines that are characterized by the presence of the triatomic grouping $\text{R}_1\text{R}_2\text{C}=\text{NNH}_2$ [1]. Hydrazones and their derivatives command an eminent position amongst organic compounds because of their analytical and industrial potential and biological activities including antimicrobial, anticonvulsant, antitubercular, analgesic, antiplatelet, anti-inflammatory, anti-proliferative, antitumoral and anti-parasitic activities [2-6]. They are also used in plasticizers, polymerization initiators, stabilizers for polymers, antioxidants, etc. [7]. According to an insightful biological view, many of the hydrazones are physiologically active and possess application in the treatment of numerous dreaded diseases; they show hypotensive action, spasmolytic activity and activity against leukemia, sarcomas and other malignant neoplasms [8,9]. Further, they act as acaricides, herbicides, antibacterial agents, plant growth regulators, nematocides, rodenticides and insecticides [10,11,9].

Over the years, the role of these compounds in the field of coordination chemistry has emerged in new dimensions because of the fact that they exhibit different ligational behaviour towards various metal ions and novel structural features manifest in the metal complexes [12-16]. Hydrazones have a wide range of applications in synthetic chemistry for the preparation of novel structurally diversified compounds, for the identification and isolation of carbonyl compounds in analytical chemistry and for the detection and determination of several metal ions. They also find applications as indicators and spot test reagents [17-19]. Furthermore, it has been recently proven that hydrazones together with pyridoxal isonicotinoyl hydrazone (PIH) analogues are powerful iron chelators *in vivo* and *in vitro* and can be of value for the treatment of iron overload [20]. Metal complexes of hydrazones have proved to have potential applications as catalysts [21], molecular sensors [22] and luminescent probes [23].

Despite the fact that these compounds have been endowed with different types of biological activity, the detailed chemistry of their action remains obscure. In order to gain more mechanistic aspects, coordination chemists have been showing great interest and effort in the synthesis and structural elucidation of metal complexes obtained from these ligands, and these studies would throw light on these properties in which the ligands are known for. Partaking of the interest in this regard, we have synthesized the metal complexes of 2-aminonicotinaldehyde benzoxazinonyl acetic acid hydrazone and obtained their structural characterization based on physico-chemical data. These studies have been explored by the biological screening of the ligand and its metal complexes and compared with data from theoretical studies (DFT and molecular docking).

5.1 Results and discussion

The ligand, 2-aminonicotinaldehyde benzoxazinonyl acetic acid hydrazone (ABAH) and its metal complexes are stable at room temperature and are non-hygroscopic. They decompose without melting, on heating. The ligand is soluble in methanol, ethanol, dimethyl sulfoxide and dimethylformamide. In the case of complexes, they are soluble in dimethyl sulfoxide and dimethylformamide. The analytical data of the compounds are presented in Table 5.1. It is clear from the table that the theoretical values calculated for the composition shown of each of the complexes are in good agreement with experimental values. The conductance measurements of the metal complexes in DMF solution were made at 10^{-3} mol.dm $^{-3}$ concentrations. All the complexes show only residual molar conductance values ($12-19\text{ ohm}^{-1}\text{ cm}^2\text{ mol}^{-1}$) so they could be considered non-electrolytes in this solvent. This implies that two chloride molecules associated with the complexes are present inside the coordination sphere.

Table 5.1 Analytical, molar conductance and physical parameters for the ligand and its metal complexes

| Molecular formula | Elemental analyses: Found (Calculated) | | | | |
|--------------------------|--|------------------|----------------|------------------|--|
| | C | N | H | M | Molar Cond. ($\text{ohm}^{-1}\text{ cm}^2\text{ mol}^{-1}$) |
| [Co(ABAH) $_2$ Cl $_2$] | 49.35 (49.24) | 17.96 (17.95) | 3.99 (3.87) | 7.68 (7.55) | 14 |
| [Ni(ABAH) $_2$ Cl $_2$] | 49.39 (49.26) | 18.01 (17.95) | 3.90 (3.88) | 7.62 (7.52) | 17 |
| [Cu(ABAH) $_2$ Cl $_2$] | 49.03 (48.95) | 17.98 (17.84) | 3.99 (3.85) | 8.15 (8.09) | 13 |
| [Zn(ABAH)Cl $_2$] | 41.72 (41.63) | 15.19 (15.17) | 3.36 (3.28) | 14.27 (14.16) | 19 |
| [Cd(ABAH)Cl $_2$] | 37.82 (37.78) | 13.81 (13.77) | 3.05 (2.97) | 22.28 (22.10) | 15 |
| [Pd(ABAH)Cl $_2$] | 38.31 (38.23) | 13.99 (13.93) | 3.10 (3.01) | 21.32 (21.17) | 12 |
| ABAH | 59.15 (59.07) | 21.65 (21.53) | 4.68 (4.65) | --- | --- |

5.1.1 Spectroscopy

The important absorption frequencies of ABAH and its metal complexes are given in Table 5.2. Ligand ABAH exhibited medium or small bands at 3400 and 3200 cm^{-1} which is attributed to free N-H stretching [24] and H-bonded ring N-H stretching [25]. A strong band at 1670 cm^{-1} is due to C=O of ring amide [26]. All these vibrational bands remain unshifted in the complexes suggesting non-involvement of these groups in coordination. However, the ligand display a medium intensity bands at 1580 cm^{-1} and 1610 cm^{-1} corresponding to C=O of aliphatic amide [27] and C=N of azomethine; these bands suffers considerable (about 40-50 cm^{-1}) lower shift in the complexes, implying the coordination through oxygen of aliphatic amide and nitrogen of azomethine groups. ABAH which had a band at 3320 cm^{-1} due to $\nu(\text{NH}_2)$ remains unshifted in the complexes [28]. The bands that appear around 480-500 cm^{-1} , 370-390 cm^{-1} and 280-300 cm^{-1} in the complexes have been assignable to $\nu(\text{M}-\text{O})$, $\nu(\text{M}-\text{N})$ and $\nu(\text{M}-\text{Cl})$ vibrations, respectively [29-31]. From the above discussion, it may be concluded that the ligand act as neutral, bidentate coordinating through oxygen of aliphatic amide and nitrogen of azomethine groups. The UV-Visible spectral data of the complexes and their assignments along with the corresponding ligand field parameters are presented in Table 5.3. The electronic spectra of the ligand exhibit strong bands at 36000 cm^{-1} ($\pi^* \leftarrow \pi$) and 33000 cm^{-1} ($\pi^* \leftarrow \text{n}$) transitions, respectively. Co(II) complex displays three bands around 8500, 17000 and 20000 cm^{-1} which may be assigned to spin-allowed transitions $^4\text{T}_{2g}(\text{F}) \leftarrow ^4\text{T}_{1g}(\text{F}) (\vartheta_1)$, $^4\text{A}_{2g}(\text{F}) \leftarrow ^4\text{T}_{1g}(\text{F}) (\vartheta_2)$ and $^4\text{T}_{1g}(\text{P}) \leftarrow ^4\text{T}_{1g}(\text{F})$, respectively, which is characteristic of octahedral geometry [32,33]. Ni(II) complex shows three peaks that appeared at 9280, 14550 and 25600 cm^{-1} . These have been assigned, respectively, to the transitions $^3\text{T}_{2g}(\text{F}) \leftarrow ^3\text{A}_{2g}(\text{F})$, $^3\text{T}_{1g}(\text{F}) \leftarrow ^3\text{A}_{2g}(\text{F})$ and $^3\text{T}_{1g}(\text{P}) \leftarrow ^3\text{A}_{2g}(\text{F})$ of octahedral geometry [34]. The octahedral geometry of Co(II) and Ni(II) complexes are further supported by the ratio of $\vartheta_2 / \vartheta_1$ values (2.04, 1.57). Various ligand field parameters viz., Racah inter-electronic repulsion parameter (B), ligand field splitting energy (10 Dq) and nephelauxetic effect (β) have been calculated. The values of B (870 and 821 cm^{-1}) for Co(II) and Ni(II) complexes are found to be lower than free ion value of 971 cm^{-1} , which is an indication of orbital overlap and delocalization of d orbitals. The nephelauxetic effect of Jorgenson [35] is derived in terms of parameter β which is the ratio of B and B'. It has been argued that the decrease in the value of β is a measure of covalency. β (0.77 and 0.797) values observed for the Co(II) and Ni(II) complexes are less than one suggesting a considerable amount of covalent character of the metal-ligand bands. The Cu(II) complex reveals a peak at 18351

cm^{-1} ($^2\text{B}_{2g} \leftarrow ^2\text{B}_{1g}$) and a shoulder on the lower energy side at 13825 cm^{-1} ($^2\text{E}_g \leftarrow ^2\text{B}_{1g}$), respectively to indicate distorted octahedral geometry [36]. Zn(II) and Cd(II) complexes show no d-d bands as in the case with a d^{10} system, however, and the peak at 30500 cm^{-1} is due to charge transfer. Tetrahedral geometry has been proposed based on spectroscopic techniques [28]. The Pd(II) complex shows three peaks at 14560 cm^{-1} ($^1\text{A}_{2g} \leftarrow ^1\text{A}_{1g}$), 16700 cm^{-1} ($^1\text{B}_{1g} \leftarrow ^1\text{A}_{1g}$) and 24870 cm^{-1} ($^1\text{E}_g \leftarrow ^1\text{A}_{1g}$), respectively these transitions are characteristic of square-planar geometry [31]. Further, the band at 28500 cm^{-1} is due to charge transfer. Further, $\vartheta_2 / \vartheta_1$ value observed for the complex is 1.15 which also supports the square-planar geometry. The experimental magnetic moment data were obtained at room temperature and the results are listed in Table 2. The magnetic moment values found for Co(II) and Ni(II) complexes are 4.21 and 3.23 B.M, respectively indicate that they are paramagnetic with magnetic moments usually observed for octahedral complexes [37,38]. The magnetic moment value of Cu(II) complex is found as 1.81 B.M. The value is close to spin-only value with a slight allowance for magnetic moment from spin-orbit coupling. The magnetic moment value suggests either square-planar or distorted octahedral geometry around Cu(II) complex [36]. Zn(II), Cd(II) and Pd(II) complexes are diamagnetic in nature.

The EPR spectrum of Cu(II) complex has been obtained in solid state and the geometrical parameters were determined. The results are listed in Table 5.4 and EPR spectrum is shown in Fig. 5.1. The EPR spectrum of Cu(II) complex is anisotropic and shows two peaks, one of intense absorption at high field and the other of less intensity at low field. Following Kneubuhl's method [39], the g values: g_{\parallel} and g_{\perp} have been calculated. From these values, g_{ave} has been calculated using the equation.

$$g_{\text{ave}} = 1/3 (g_{\parallel} + g_{\perp})$$

The g value of Cu(II) complex can be used to derive the ground state [40]. In tetragonally elongated octahedral complexes, $g_{\parallel} > g_{\perp} > 2$ with $d_{x^2-y^2}$ orbital have unpaired electron. In a tetragonally compressed octahedron, on other hand, the unpaired electron lies in d_z^2 orbital with $g_{\perp} > g_{\parallel} = 2$. The experimental g values for the Cu(II) complex are $g_{\parallel} = 2.19$ and $g_{\perp} = 2.05$ indicating that $g_{\parallel} > g_{\perp} > 2$, suggesting elongated distorted octahedral geometry and that the unpaired electron lies in $d_{x^2-y^2}$ orbital [41]. The EPR isotropic parameters $g_{\text{ave}} = 2.10$, $A_{\text{ave}} = 71$, other parameters follow the order $A_{\parallel} = 158 \text{ cm}^{-1} > A_{\perp} = 28 \text{ cm}^{-1}$ under investigation of Cu(II) complex.

The metal-ligand σ -bonding parameter (α^2), in plane π -bonding parameter (β^2) and γ^2 out of plane π -bonding for the complexes have been obtained using the simplified equations [42].

$$\alpha^2 = (A_{\parallel}/0.036) + (g_{\parallel} - 2.0027) + 3/7 (g_{\perp} - 2.0027) + 0.04$$

$$\beta^2 = (g_{\parallel} - 2.0027)E / (-8 \alpha^2) \text{ and}$$

$$\gamma^2 = (g_{\parallel} - 2.0027)E / (-2\lambda\alpha^2)$$

Where, $\lambda = -828 \text{ cm}^{-1}$ for free copper ion and E is electronic transition energy. A value of $\alpha^2 = 0.5$ indicates 100% covalent nature, while $\alpha^2 = 1$ indicates complete ionic character. The α^2 and γ^2 parameters are similarly a measure of covalency in the in-plane and out-of plane π -bonding, respectively. β^2 or $\gamma^2 = 1$ indicates total ionic character and β^2 and $\gamma^2 = 0.5$ corresponds to a total covalent character. The observed α^2 value for the Cu(II) complex is 0.69 indicative of strong/appreciable in-plane σ -bonding. The β^2 and γ^2 values are 0.61 and 0.77, respectively which suggest appreciable/moderate in-plane and out-of-plane π -bonding. This is further confirmed by orbital reduction parameters r_{\parallel} and r_{\perp} , which are calculated using the expressions, $r_{\parallel} = \alpha^2\beta^2$ and $r_{\perp} = \alpha^2\gamma^2$, for in-plane π -bonding $r_{\parallel} < r_{\perp}$ and for out-of-plane π -bonding $r_{\perp} < r_{\parallel}$. The observed r_{\parallel} and r_{\perp} values are 0.53 and 0.66, respectively, revealing that the present complex is in-plane π -bonded type. Further, λ (spin-orbit coupling constant) value for the present complex is (-322 cm^{-1}) which is less than the free ion value ($\lambda_0 = -828 \text{ cm}^{-1}$) indicating considerable mixing of ground and excited terms. ^1H NMR spectrum of the ligand ABAH show the signals at 8.72, 7.39 ppm corresponding to azomethine and NH_2 protons, respectively, the ^1H NMR spectrum as shown in Fig. 5.2

5.2 DFT studies

5.2.1 Quantum chemical calculations

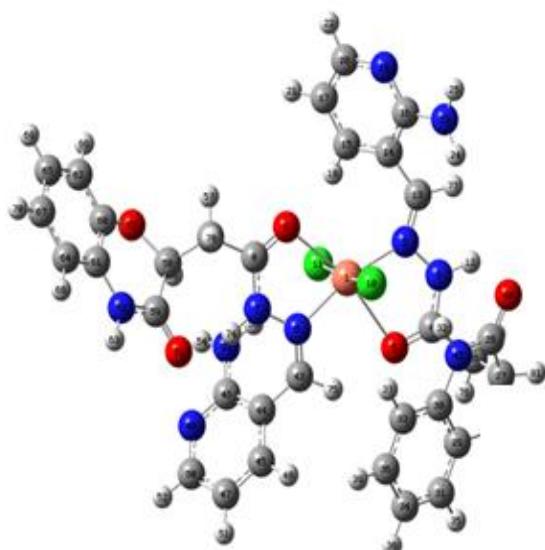

DFT geometric optimization and frequency calculations were performed for ligand and its metal complexes analogues with Gaussian o9W software package. DFT/B3LYP functional was used, with 6-311++G(d,p) basis set for the ligand and SDD basis set for its metal complexes analogues. The optimized geometric structure was obtained by solving self-consistent field equations iteratively; on geometry optimization, the global minimum was found to be -1118.48456 Hartree, -3302.38148 Hartree, -3327.45035 Hartree, -3353.84579 Hartree, -2265.016902 Hartree, -2205.65174 Hartree and -2166.385111 Hartree, respectively for the ligand [ABAH], Co(II), Ni(II), Cu(II), Zn(II), Cd(II) and Pd(II) complexes, respectively as shown in Fig. 5.3 along with numbering of atoms. The selected structural parameters of metal complexes moiety are listed in Tables 5.5-5.6.

5.2.2 Molecular Electrostatic Surface Potential

The molecular electrostatic surface potential (MESP) provides the electrons and nuclei of a molecule made in the surrounding region are well built as a guide to the elucidation and forecast of molecular reactive behavior. It is through this potential $V(r)$ is given by

$$V(r) = \sum_A \frac{Z_A}{|R_A - r|} - \int \frac{\rho(r')}{|r' - r|} dr'$$

Where $\rho(r')$ is the electronic density function of the molecule and Z_A is the charge on nucleus A, located at R_A ; for studying both nucleophilic and electrophilic character $V(r)$ is a useful tool which can be determined either computationally or experimentally by diffraction methods [43-45]. The different values of electro static potential are characterized by different

colors; blue color represents positive electrostatic potential, green represents the region of zero potential, yellow represents slight electron negative and red represents the maximum negative regions of electrostatic potential. The potential increases from red to blue in the order: red < orange < yellow < green < blue [46,47]. The various regions on the surface of the molecule which denotes electrophilic and nucleophilic regions are shown by red and blue colors, respectively. Any region there which has no electrostatic potential would be represented by green color. The MESP of the compounds are represented in Fig. 5.4.

5.2.3 Non-linear optical (NLO) behaviour

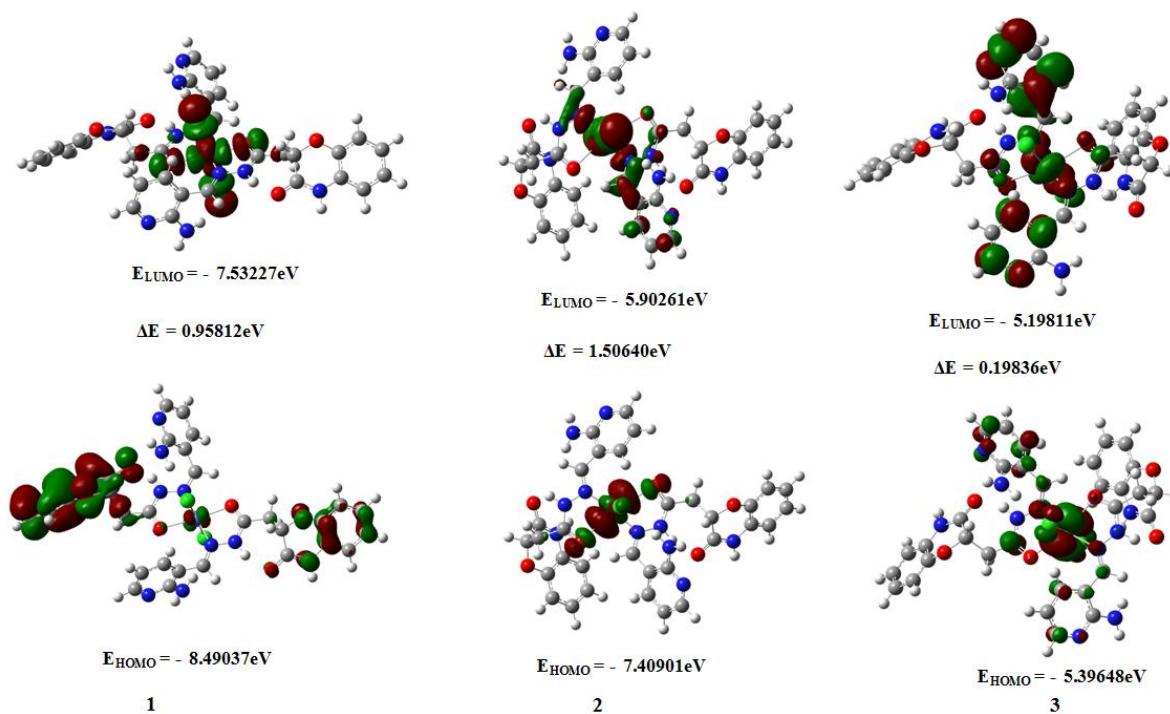

As the electromagnetic radiation passes through a non-linear optical (NLO) material, it interacts with the material. As a result, it experiences a change in frequency, amplitude, phase or other propagation characteristics giving rise to new fields [48]. This property of NLO materials has been extensively exploited in the fields of telecommunications, signal processing and optical inter-connections. They play a key role in providing important functions such as frequency shifting, optical logic, optical switching and optical memory [49-52]. The value of first order hyperpolarizability is a measure of NLO behaviour. Hence, DFT has been used extensively to investigate organic NLO materials [53-57]. The NLO parameters such as total molecular dipole moment (μ_t) and its components; total molecular polarizability (α_t) and its components; anisotropy of polarizability ($\Delta\alpha$); and first order static hyperpolarizability (β_t) were calculated using DFT approach and the results are available in Table 5.7. It is usual practice to determine the NLO behaviour of given compounds by comparing its total molecular dipole moment and mean first order hyperpolarizability with the corresponding values of urea, which are 1.3732 Debye and 0.3728×10^{-30} cm⁵/esu, respectively. For ABAH, the value of μ_t is 4.2890 Debye and that of β_t is 6.094×10^{-30} cm⁵/e.s.u. Thus μ_t and β_t for ABAH are 3.1 and 16 times that of corresponding values for Urea. Similarly, for metal complexes, the values of μ_t and β_t are 4.8978 Debye and 10.551×10^{-30} cm⁵/e.s.u [for Co(II)], 6.5745 Debye and 8.679×10^{-30} cm⁵/e.s.u [for Ni(II)], 4.1649 Debye and 9.510×10^{-30} cm⁵/e.s.u [for Cu(II)], 14.7174 Debye and 7.596×10^{-30} cm⁵/e.s.u [for Zn(II)], 16.4889 Debye and 9.051×10^{-30} cm⁵/e.s.u [for Cd(II)] and 18.5557 Debye and 10.090×10^{-30} cm⁵/e.s.u [for Pd(II)], respectively. From the above results, it is observed that μ_t and β_t values for the complexes are greater than that for free ligand; hence all the compounds exhibit NLO properties. The values of hyperpolarizability are a measure of NLO activity of the molecular system. It is associated with intra-molecular charge transfer that is attributed to electron cloud movement through π - conjugated framework of electrons [58]. Hence the ligand and its metal complexes are a strong candidate for the development of new NLO materials based on the values of the dipole moment and first order hyperpolarizability.

Table 5.7 The values of dipole moment μ_t (in Debye); polarizability α_t and first order hyperpolarizability β_t (in $10^{-30} \text{cm}^5/\text{e.s.u}$) of ABAH and its metal complexes

5.2.4 Frontier molecular orbitals

The Frontier orbitals HOMO and LUMO are the important factors in quantum chemistry as these determine the way a molecule interacts with other species. The frontier orbital gap is used as an indicator for chemical reactivity and chemical stability of the molecule. Generally, a molecule with a small frontier orbital gap is readily polarizable and normally exhibits high chemical reactivity and low kinetic stability [59-61]. The results are presented in Table 5.8 and Fig. 5.5. From the observed quantum chemical calculations, frontier orbitals energy gap was found in the order of ABAH > Zn(II) > Ni(II) > Co(II) > Cd(II) > Pd(II) > Cu(II). A molecule with a lower frontier orbital gap is generally associated with chemical reactivity and low kinetic stability. The frontier molecular orbital gap of metal complexes are small compared to ligand; hence metal complexes are more polarizable than ligand. It is seen from Table 5.8, that the chemical potential of the compounds is negative, which signifies that the compounds are stable.

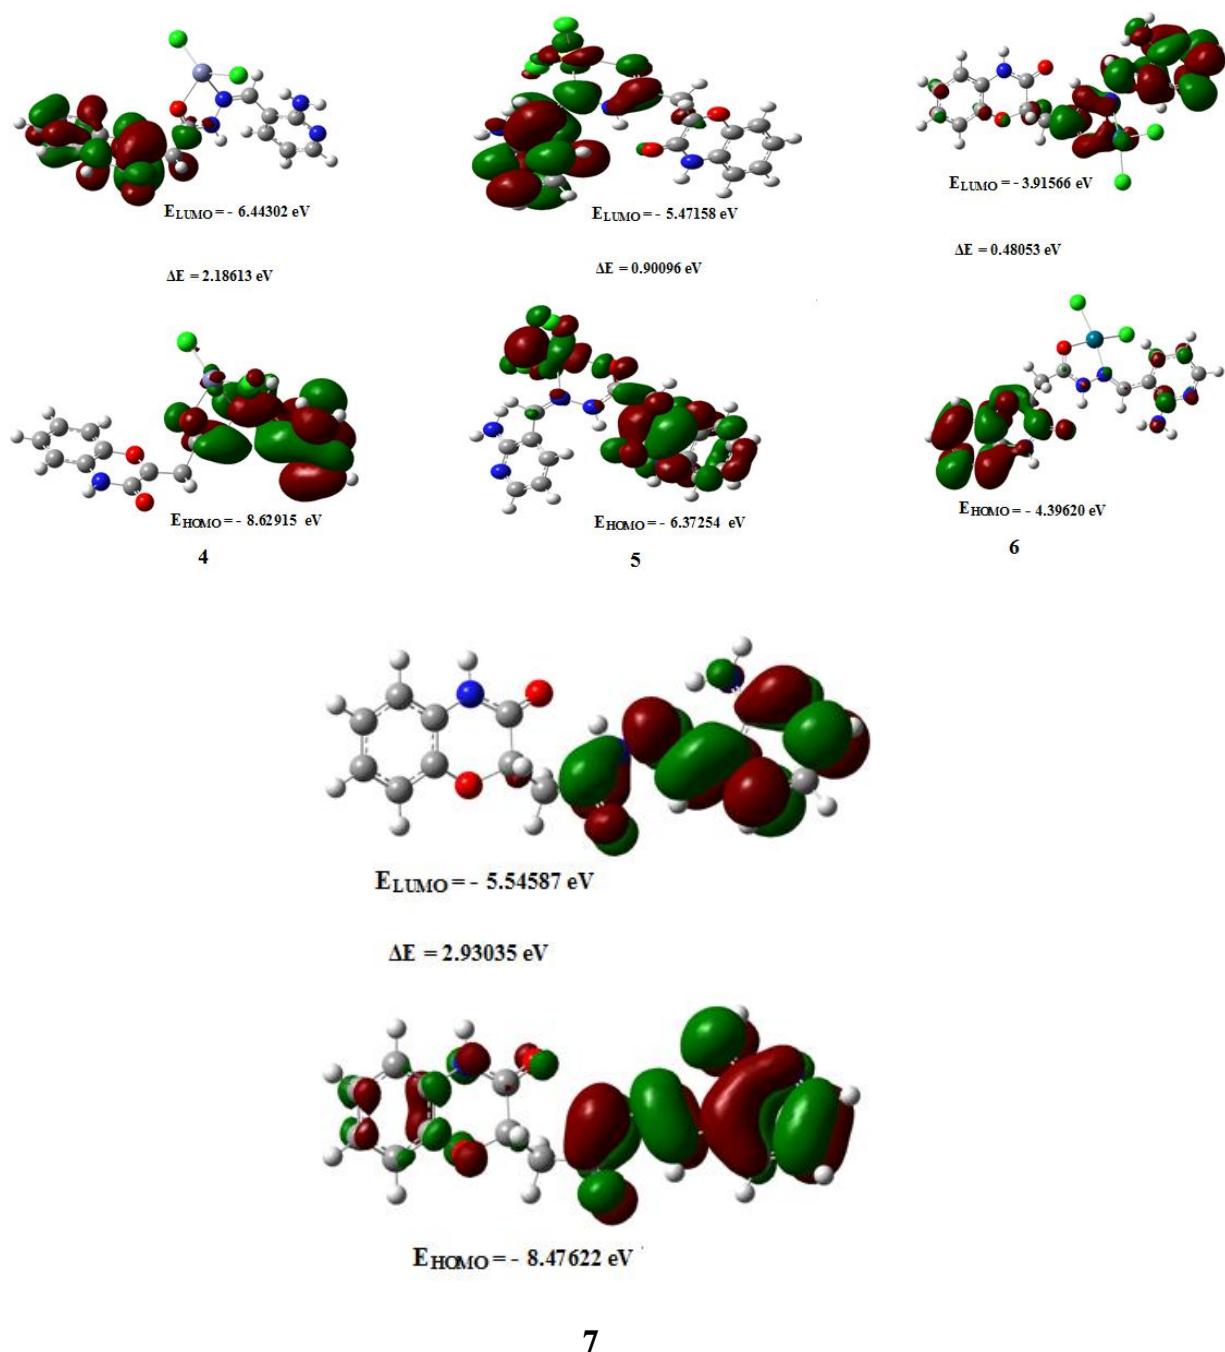

Fig. 5.5 Frontier molecular orbital's of (1) Co(II), (2) Ni(II), (3) Cu(II), (4) Zn(II), (5) Cd(II), (6) Pd(II) complexes and (7) ligand ABAH.

5.3 Biological evaluations

5.3.1 Antimicrobial activity

The synthesized compounds have been assessed for their *in vitro* antimicrobial activity against both gram-negative (G⁻) bacteria [*Pseudomonas aeruginosa*, *Klebsiella pneumoniae* and *Escherichia coli*] and gram-positive (G⁺) bacteria [*Bacillus subtilis*, *Staphylococcus aureus* and *Staphylococcus epidermidis*] and different fungal strains [*Aspergillus niger*, *Aspergillus flavus*, *Curvularia lunata*, *Rhizoctonia bataticola* and *Candida albicans*] via the disc approach through the use of Streptomycin and Nystatin as reference controls. The minimum inhibitory concentrations (MICs) for all the tested compounds have been suggested in $\mu\text{g}/\text{mL}$, and the outcomes are illustrated in Table 5.9 and Table 5.10. It's far obvious from the tables that the synthesized compounds exerted significant *in vitro* antimicrobial activity against almost all the tested bacterial and fungal strains. Among the tested compounds, Co(II) complex observed to be efficient and exhibited equipotent inhibitory efficacy and broader antibacterial activity than that of the reference drug. The Co(II) complex showed excellent activity than the standard drug Streptomycin against *E. coli* with MIC values of 2.68 $\mu\text{g}/\text{mL}$, and most potent activity against gram-positive and gram-negative bacterial strains such as *S. aureus*, *B. subtilis*, *S. epidermidis*, *K.*

pneumoniae and *P. aeruginosa* with MIC values of 3.15, 7.46, 3.88, 5.62 and 8.57 $\mu\text{g/mL}$, respectively compared to standard drug. Cd(II) complex exhibited a broad spectrum of activity against *S. aureus* (MIC = 3.64 $\mu\text{g/mL}$), *B. subtilis* (MIC = 9.37 $\mu\text{g/mL}$), *S. epidermidis* (MIC = 4.70 $\mu\text{g/mL}$), *K. pneumoniae* (MIC = 6.55 $\mu\text{g/mL}$), *E. coli* (MIC = 3.18 $\mu\text{g/mL}$), and *P. aeruginosa* (MIC = 14.06 $\mu\text{g/mL}$), respectively. Zn(II) complex against *S. aureus* (MIC = 6.28 $\mu\text{g/mL}$) and *E. coli* (MIC = 5.16 $\mu\text{g/mL}$), Pd(II) complex against *K. pneumoniae* (MIC = 9.58 $\mu\text{g/mL}$) showed modest activity, while the rest of the compounds [ABAH, Ni(II) and Cu(II)] exhibited marginal activity against the microorganisms tested. The antifungal activity of the complexes, Co(II) complex against *A. flavus* and Zn(II) complex against *C. albicans* was potent with MIC values of 4.67 and 10.99 $\mu\text{g/mL}$, respectively compared to positive control Nystatin. In addition, Co(II) complex reported good activity against *A. niger* (MIC = 9.12 $\mu\text{g/mL}$), *C. lunata* (MIC = 8.61 $\mu\text{g/mL}$) and *C. albicans* (MIC = 13.85 $\mu\text{g/mL}$), while Zn(II) complex also showed good activity against *A. niger* (MIC = 9.59 $\mu\text{g/mL}$) and *A. flavus* (MIC = 5.73 $\mu\text{g/mL}$), respectively. The remaining compounds exhibited poor activity against the tested fungi strains.

From the results it is apparent that the metal complexes exert more antimicrobial activity than the ligand, indicating that the metals are actually in action. It is assumed that the role of a ligand associated with the metal ion in a complex is to make the metal ion fat soluble. It may be expected that the capability of a ligand that forms negative ion upon deprotonation in making the metal ion fat soluble is more owing to the fact that such a ligand would perfectly neutralize the positive charge on metal ion and make the complex neutral as a whole. Once the complex makes its way across the cell membrane, depending on the environment there, it undergoes dissociation releasing the metal ion and enabling it to exert its toxic effect.

5.3.2 Antioxidant activity

The antioxidant activity of the new compounds was investigated for their antioxidant ability and this was carried out using DPPH (1,1-diphenyl-2-picrylhydrazyl) method where ascorbic acid was chosen as a reference drug. The ligand and its metal complexes were performed in triplicate and the standard deviation was calculated. The activity results are expressed in terms of IC₅₀. IC₅₀ (μM) values were given in Table 5.11 and Fig. 5.6. From the evaluation of antioxidant activity, Ni(II) complex exhibited potent activity as observed in IC₅₀ value of 18.35 ± 0.28 μM; this IC₅₀ value of Ni(II) complex is close to reference ascorbic acid IC₅₀. Cu(II) complex showed good activity at an IC₅₀ value of 20.17 ± 1.28 μM, while moderate activity was observed for other complexes with IC₅₀ values of 28.09 ± 0.55

μM [Co(II)], $39.40 \pm 1.13 \mu\text{M}$ [Zn(II)], $35.16 \pm 1.26 \mu\text{M}$ [Cd(II)], $50.83 \pm 0.27 \mu\text{M}$ [Pd(II)] and $50.91 \pm 0.18 \mu\text{M}$ [ABAH], respectively. The above experimental results investigated that the order of activity of the compounds was: Ni(II) > Cu(II) > Co(II) > Cd(II) > Zn(II) > Pd(II) > ABAH.

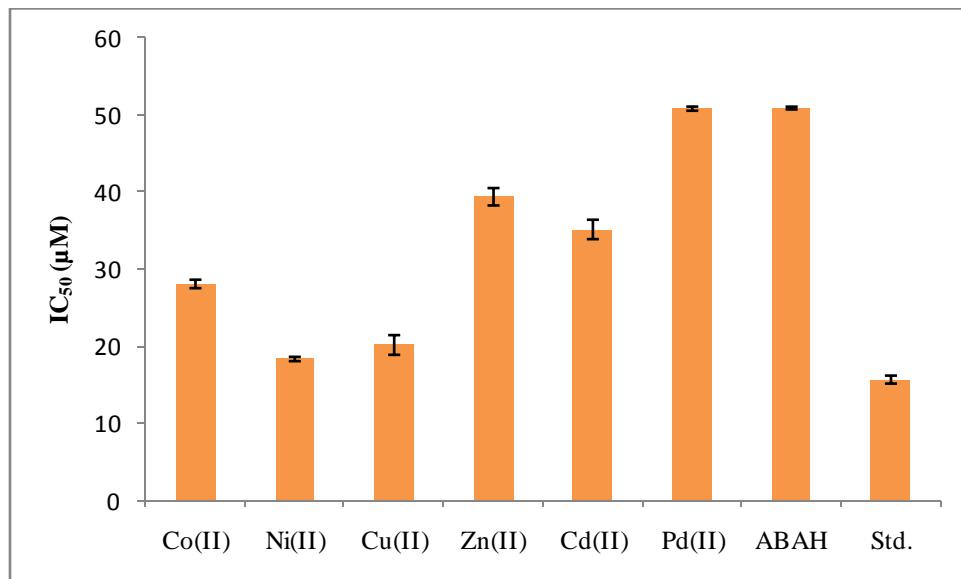

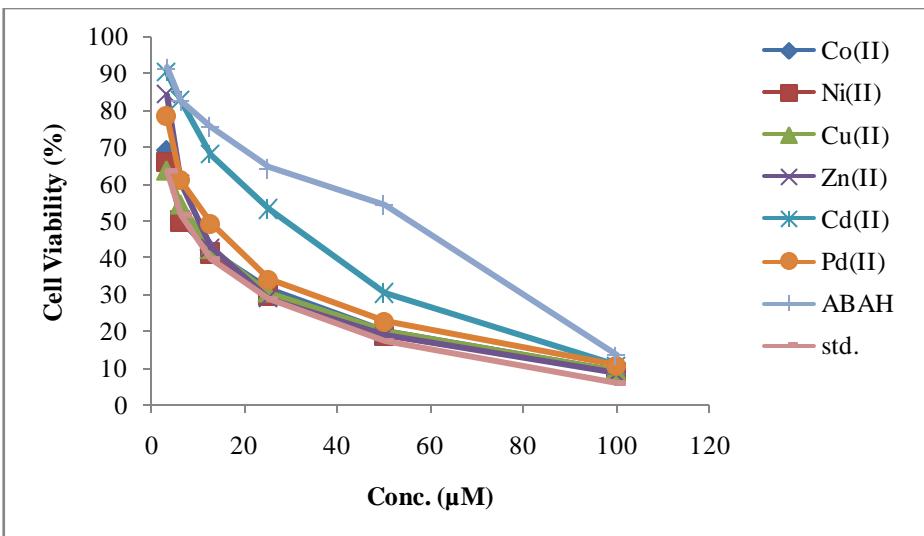

Fig. 5.6 Scavenging activity of the ligand and its complexes

Table 5.11 DPPH scavenging capacities (IC₅₀, μM) of ligand and its metal complexes

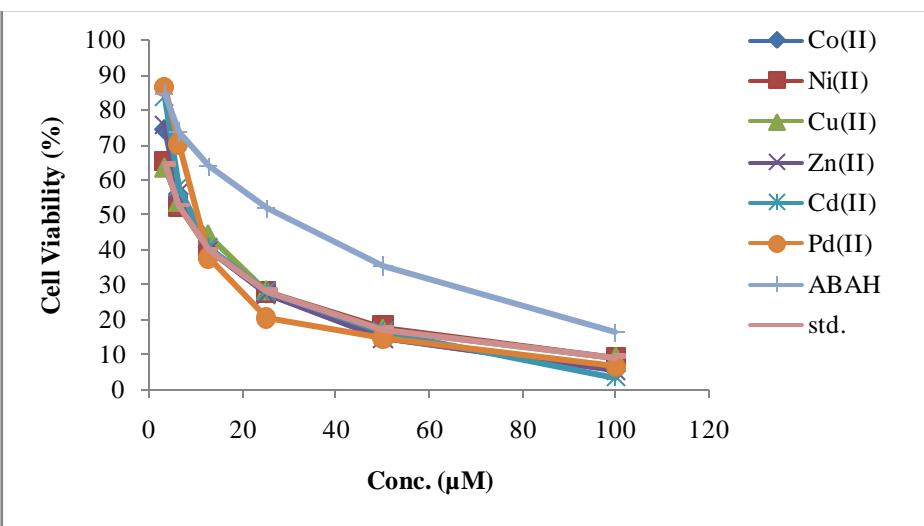

| Compounds | IC ₅₀ (μM) |
|---------------|------------------------------------|
| Co(II) | 28.09 \pm 0.55 |
| Ni(II) | 18.35 \pm 0.28 |
| Cu(II) | 20.17 \pm 1.28 |
| Zn(II) | 39.40 \pm 1.13 |
| Cd(II) | 35.16 \pm 1.26 |
| Pd(II) | 50.83 \pm 0.27 |
| ABAH | 50.91 \pm 0.18 |
| Ascorbic acid | 15.68 \pm 0.52 |

5.3.3 Cytotoxic activity

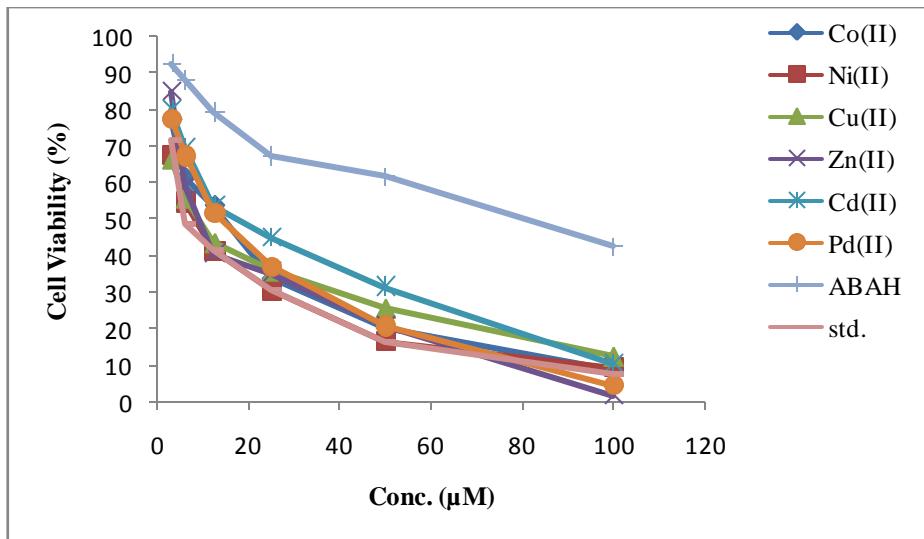

The cytotoxicity of the compounds was carried out against different human cancer cell lines MCF-7 (breast), HeLa (cervical), A549 (lung), HepG-2 (liver), IMR-32 (neuroblastoma) and HEK293 (embryonic kidney) using MTT-microcultured tetrazolium assay. The relationship between surviving fraction and drug concentration was plotted to obtain the survival curve of MCF-7, HeLa, A549, HepG2 and IMR-32 are shown in Fig 5.7. The IC₅₀ values for compounds are represented in Table 5.12. From the cytotoxic activity results, Ni(II) complex exhibited equal level of anticancer activity compared to cisplatin with IC₅₀ values of $8.60 \pm 0.15 \mu\text{M}$ (IMR-32), $4.17 \pm 0.13 \mu\text{M}$ (HeLa), $4.92 \pm 0.21 \mu\text{M}$ (MCF-7), $7.72 \pm 0.24 \mu\text{M}$ (A549), $3.01 \pm 1.13 \mu\text{M}$ (HepG-2), respectively. The Cu(II) complex showed a broad spectrum of activity at IC₅₀ values of $10.46 \pm 1.01 \mu\text{M}$, $5.70 \pm 1.12 \mu\text{M}$, $6.44 \pm 0.41 \mu\text{M}$, $12.35 \pm 1.17 \mu\text{M}$ and $3.96 \pm 0.61 \mu\text{M}$ against IMR-32, HeLa, MCF-7, A549 and HepG-2, respectively. Zn(II) complex against IMR-32 (IC₅₀ = $17.55 \pm 0.22 \mu\text{M}$), Co(II) complex against MCF-7 (IC₅₀ = $7.62 \pm 0.19 \mu\text{M}$), and HepG-2 (IC₅₀ = $5.14 \pm 1.06 \mu\text{M}$) exhibited high activity. The remaining compounds showed moderate to poor activity with IC₅₀ values ranging from $20.56 \pm 0.43 \mu\text{M}$ to $78.69 \pm 0.83 \mu\text{M}$. The potent complexes Ni(II) and Cu(II) are also tested anticancer activity against normal cell line HEK293 with IC₅₀ values of $91.84 \pm 0.26 \mu\text{M}$ and $85.67 \pm 0.13 \mu\text{M}$, respectively indicate that the potent complexes are nontoxic.

Values are expressed in mean ± SD of three replicates. ND stands for not determine

5.3.4 Molecular docking

The *in silico* molecular docking analysis of the ligand ABAH and its metal complexes against human epidermal growth receptor (HER2) and epidermal growth factor receptor (EGFR) was carried out to verify the relation between *in vitro* antiproliferative activity results and binding affinities of the inhibitors using AutoDock program. HER2 contained the trans membrane tyrosine kinase receptor. It can regulate normal cell growth and is useful in its development also. It can dimerize without any ligand. The receptor dimerization leads to autophosphorylation and results in cell-cycle progression *via* delocalization and degradation of cell-cycle inhibitor p27Kip1, angiogenesis, cell differentiation, invasion, proliferation, etc. HER2 is also associated with breast, ovarian and gastric cancers. Hence, without dimerization HER2 becomes inactive [62]. EGFR contains an intracellular tyrosine kinase domain and extracellular ligand binding domain. They are stabilized by disulphide structures. Its overexpression leads to tumor, non-small-cell lung cancer (NSCLC) because it plays a major role in signal transduction pathways accompanied with cell growth, differentiation, survival [63,64]. Hence, HER2 and EGFR are the best biological targets for the discovery and development of dual inhibitors [65].

The comparative molecular docking studies of the complexes and the ligand with the protein receptors HER2 and EGFR (Table 5.13) obviously suggest that the affinity of target

compounds towards protein receptor HER2 is better than that of protein receptor EGFR. Hence HER2 was taken as target protein receptor for the discussion. Docking studies revealed that the complexes Ni(II) and Cu(II) exhibited least binding energies i.e. -10.11 kcal/mol and -10.68 kcal/mol, respectively against HER2.

Besides, Ni(II) complex exhibited ten hydrogen bonds; one strong hydrogen bond between the amine group of 2-aminopyridyl ring and amino acid residue ASP855 with a bond length of 1.88 Å, one strong hydrogen bond between the $-NH$ group of oxazinone ring and amino acid residue ALA722 with a bond length 2.13 Å, one hydrogen bond between $-O$ -atom of oxazinone ring with amino acid residue ARG841 with a bond length 2.16 Å, one hydrogen bond between carbonyl oxygen atom of oxazinone ring and amino acid residue LYS745 with a bond length 2.17 Å, one hydrogen bond between $-NH$ group of imine moiety with amino acid residue ASN842 with a bond length 2.63 Å, two hydrogen bonds between carbonyl oxygen adjacent to imine moiety and amino acid residue LYS745 with a bond length 2.97 Å and 3.05 Å, respectively, one hydrogen bond between $-CH$ group of 2-aminopyridyl ring with amino acid residue CYS797 with a bond length 3.23 Å and one hydrogen bond between 2-aminopyridyl ring and amino acid residue CYS797 with a bond length 3.83 Å. The phenyl ring in the benzoxazinone ring interacts with the amino acid residues PHE723, LEU844, LEU718 and ALA743; the pyridyl ring interacts with amino acid residues VAL726 and LYS745 through hydrophobic interactions. In addition to this, there was an electrostatic interaction between the $-NH$ group of imine moiety with the amino acid residue ASP855.

The Cu(II) complex exhibited five hydrogen bonds; one hydrogen bond between amine group of 2-aminopyridine ring and amino acid residue ASN842 with a bond length 1.96 Å, one hydrogen bond between carbonyl oxygen of oxazinone ring and amino acid residue LYS745 with a bond length 1.96 Å, one hydrogen bond between amine group of 2-aminopyridyl ring and amino acid residue ASP855 with a bond length 1.98 Å and one carbon-hydrogen bond between $-NH$ group of oxazinone ring and amino acid residue ASP855 with a bond length 2.02 Å, and one hydrogen bond between $-CH$ group of 2-amino pyridine ring and amino acid residue of ALA722. The phenyl ring interacts with the amino acid residues LEU718 and LEU777 and the pyridyl ring interacts with amino acid residues LEU718, LEU844 AND ALA743 through hydrophobic interactions. The molecular docking results for ligand ABAH and its complexes against HER2 and EGFR are shown in Table

5.13. The hydrogen bonding interactions and hydrophobic interactions of Ni(II) and Cu(II) complexes are shown in Fig.s 5.8-5.21.

5.4 Conclusions

We have synthesized novel metal complexes of 2-aminonicotinaldehyde benzoxazinonyl acetic acid hydrazone. The compounds have been structurally characterized by different physico-chemical techniques with an aim to evaluate their antioxidant, antimicrobial and cytotoxic activities as well as for purposes of DFT calculations and docking studies. The analytical data indicate 1:2 (M:L) stoichiometry in the case of Co(II), Ni(II) and Cu(II) complexes and 1:1 stoichiometry in Zn(II), Cd(II) and Pd(II) complexes; each complex further being associated with a corresponding number of anions such as chlorides. All the complexes are non-electrolytes in DMF. The ligand ABAH reacts with metal complexes in a neutral, bidentate fashion, the coordinating atoms being oxygen of aliphatic amide group and nitrogen of azomethine group. The Co(II), Ni(II) and Cu(II) complexes are paramagnetic to the extent of three, two and one unpaired electrons, respectively, while complexes of Zn(II), Cd(II) and Pd(II) are diamagnetic. Based on the spectral and DFT data the geometry of the complexes as proposed as octahedral for Co(II) and Ni(II) complexes, distorted octahedral for Cu(II) complex, tetrahedral for Zn(II) and Cd(II) complexes and square-planar for Pd(II) complex. The evaluation of ESR parameters from the ESR spectrum of Cu(II) complex indicates that the M-L bonds are covalent and out of plane π -bonded. DFT studies revealed that the ligand and its metal complexes are good precursors for the development of new NLO materials. The antimicrobial activity of the complexes Co(II) and Cd(II) showed broad and excellent antimicrobial activities against G^+ , G^- and fungal strains comparable to that of standard antimicrobial agents. The antioxidant activity of the complexes Ni(II) and Cu(II) was excellent with IC_{50} values of $18.35 \pm 0.28 \mu M$ and $20.17 \pm 1.28 \mu M$, respectively compared to ascorbic acid as a positive control. With regard to anticancer activity, Ni(II) and Cu(II) complexes exhibited potent activity against IMR-32, HeLa, MCF-7, A549 and HepG-2 cell lines compared to standard drug cisplatin. These *in vitro* anticancer studies were further supported by molecular docking. Primarily based on the above outcomes, the synthesized compounds could be potential precursors for further development of novel antimicrobial and anticancer agents.

CHAPTER-VI

Synthesis, characterization, theoretical investigation and biological screening of metal(II) complexes of derived from 4-(2-aminopyridin-3-methylene)aminobenzoic acid

2-aminonicotinaldehyde, which is structurally comparable to 2-aminobenzaldehyde and salicylaldehyde has been little investigated as a precursor for the synthesis of Schiff bases and their metal complexes. A number of reviews on Schiff base metal complexes derived from salicylaldehyde and 2-aminobenzaldehyde have been reported [1-6]. 2-aminonicotinaldehyde should form similar Schiff bases and also form complexes with several metal ions [7-10]. 2-aminonicotinaldehyde containing Schiff base ligands and their metal complexes are well recognized for their use in a variety of biological applications such as antibacterial, antimalarial, antitubercular, antifungal, antioxidant, anti-inflammatory and anticancer activities [11-15].

In particular, cancer is one of the most staggering and death causing diseases in the world which involves abnormal cell proliferation in the body [16-18]. On the one hand cisplatin and its derivatives, and on the other hand, a large number of metal complexes have been introduced in the treatment of a variety of cancers [19,20]. However, it was observed that there are several drawbacks regarding the use of complexes, which includes limiting efficiency, clinical usage and side effects [19]. Excitingly, a large number of metal complexes have been evaluated to design the molecules for high selectivity, maximum efficacy and minimum toxicity.

In view of the aforementioned biological importance of the metal complexes and Schiff bases, we present here, novel metal complexes of Co(II), Cu(II), Ni(II), Zn(II), Cd(II) and Pd(II) with Schiff base in a single molecular framework and their potential *in vitro* anticancer, antioxidant, antimicrobial activities and *in silico* studies (DFT and molecular docking).

6.1 Results and discussion

The new ligand, 4-(2-aminopyridin-3-methylene)aminobenzoic acid and its metal(II) complexes are stable at room temperature and non-hygroscopic. However, at higher temperatures, the ligand undergoes melting while the complexes decompose without melting. The ligand is soluble in MeOH, EtOH, CHCl₃, DMF, and DMSO and the complexes are only soluble in dimethyl sulfoxide and dimethylformamide. The authenticities of the synthesized compounds were ascertained using various spectroscopic methods and elemental analysis. The theoretical percent values of the elements in the complexes have been calculated for the formulations given in Table 6.1 to indicate that experimental values agree, within the experimental error, with calculated values.

Table 6.1 Analytical, molar conductance and physical parameters for the ligand and its metal complexes

| Molecular formula | Elemental analyses: Found (Calculated) | | | | |
|--|--|------------------|----------------|--------------------|--|
| | C | N | H | M | Molar Cond. ($\text{ohm}^{-1} \text{cm}^2 \text{mol}^{-1}$) |
| [Co(ANABZA) ₂ Cl ₂] | 50.93 (51.00) | 13.66 (13.72) | 3.65 (3.62) | 9.69 (9.62) | 12 |
| [Ni(ANABZA) ₂ Cl ₂] | 50.97 (51.02) | 13.67 (13.73) | 3.58 (3.62) | 9.52 (9.59) | 16 |
| [Cu(ANABZA) ₂ Cl ₂] | 50.58 (50.62) | 13.59 (13.62) | 3.55 (3.59) | 10.25 (10.30) | 19 |
| [Zn(ANABZA) ₂ Cl ₂] | 50.41 (50.47) | 13.54 (13.58) | 3.55 (3.58) | 10.50 (10.57) | 15 |
| [Pd(ANABZA)Cl ₂] | 37.37 (37.30) | 10.09 (10.04) | 2.59 (2.65) | 25.31 (25.42) | 11 |
| [Cd(ANABZA)Cl ₂] | 36.91 (36.78) | 9.98 (9.90) | 2.64 (2.61) | (26.59) (26.48) | 16 |

6.1.1 Spectroscopic characterization

The positions of the selected characteristic IR bands unambiguously unveiled the formation of new ligand 4-(2-aminopyridin-3-methylene)aminobenzoic acid and its metal complexes. The important absorption frequencies are presented in Table 6.2. The ligand showed the strong band at 1629 cm^{-1} due to $\nu(\text{C}=\text{N})$, on the other hand, this band was lowered by $20-30 \text{ cm}^{-1}$ in the complexes pointing to the fact that the nitrogen of this group is involved in binding with the metal ion [21-25]. The amine group nitrogen of the ligand showed the band at 3420 cm^{-1} due to $\nu(\text{NH}_2)$ has been found at lower frequencies by ($3401-3371 \text{ cm}^{-1}$) in the complexes, this kind of shift suggested that amine nitrogen is bonded to the metal [26,27]. The carboxylic acid ($\text{C}=\text{O}$) and ($\text{C}=\text{N}$)_{py} stretching frequencies of the ligand occurred at 1701 and 1567 cm^{-1} . These bands do not undergo any perceptible shifts in the metal complexes suggesting that there are no interactions

between oxygen and nitrogen of these groups. The aforementioned results proved that the ligand coordinate with metal ions through amine nitrogen atom and azomethine nitrogen. In the complexes, the other peaks observed in the region of $478\text{-}520\text{ cm}^{-1}$ and $275\text{-}321\text{ cm}^{-1}$ correspond to $\nu(\text{M}-\text{N})$ and $\nu(\text{M}-\text{Cl})$, respectively. The conductance measurements of the metal complexes in DMF solution were made at $10^{-3}\text{ mol}\cdot\text{dm}^{-3}$ concentrations. All the complexes show only residual molar conductance values ($11\text{-}19\text{ ohm}^{-1}\text{ cm}^2\text{ mol}^{-1}$) and hence they may be considered non-electrolytes [28,29]. This implies that both the two chloride anions associated with these complexes are present inside the coordination sphere. The electronic and magnetic data are given in Table 6.3. The UV-Visible spectrum of the ligand exhibited bands at 30390 cm^{-1} and 33245 cm^{-1} corresponding to $n \rightarrow \pi^*$ and $\pi \rightarrow \pi^*$ transitions, respectively. The electronic spectra of Co(II) complex exhibits three bands around 9000 cm^{-1} [${}^4\text{T}_{1g}(\text{F}) \rightarrow {}^4\text{T}_{2g}(\text{F})$ (ϑ_1)], 18500 cm^{-1} [${}^4\text{T}_{1g}(\text{F}) \rightarrow {}^4\text{A}_{2g}(\text{F})$ (ϑ_2)] and 20400 cm^{-1} attributable to [${}^4\text{T}_{1g}(\text{F}) \rightarrow {}^4\text{T}_{1g}(\text{P})$ (ϑ_3)], respectively, characteristic of octahedral geometry [30,31]. The octahedral geometry of Co(II) complex also supports $\vartheta_2 / \vartheta_1$ (2.02) values [32]. The Racah interelectronic repulsion parameter (B) value for Co(II) complex was found to be 756 cm^{-1} which is lower than the free ion value ($B^1 = 971\text{ cm}^{-1}$) indicating a good overlap of the orbitals involved [33]. Further, the nephelauxetic effect parameter ($\beta = B/B^1$) value (0.78) is less than one suggesting that M-L bonds are covalent in character. The Ni(II) complex exhibits three peaks in the regions 9800 , 15900 and 25800 cm^{-1} . These peaks have been attributed, respectively to the transitions ${}^3\text{A}_{2g}(\text{F}) \rightarrow {}^3\text{T}_{2g}(\text{F})$, ${}^3\text{A}_{2g}(\text{F}) \rightarrow {}^3\text{T}_{1g}(\text{F})$ and ${}^3\text{A}_{2g}(\text{F}) \rightarrow {}^3\text{T}_{1g}(\text{P})$ of octahedral geometry [34-36]. The value $\vartheta_2 / \vartheta_1$ (1.61) further supports octahedral geometry. The values of B (820 cm^{-1}) and β (0.80) observed for Ni(II) complex is indicative of the orbital overlap and M-L bonds are covalent in character [32]. The Cu(II) complex reveals a peak at 18351 cm^{-1} (${}^2\text{B}_{1g} \rightarrow {}^2\text{B}_{2g}$) and a shoulder on the lower energy side at 13825 cm^{-1} (${}^2\text{B}_{1g} \rightarrow {}^2\text{E}_g$), respectively indicates the distorted octahedral geometry around Cu(II) ion [37]. Zn(II) and Cd(II) complexes show no bands in the visible region as expected for d^{10} system and have a peak at around 28500 cm^{-1} due to charge transfer. The complexes have been assigned octahedral geometry for [Zn(II)] and tetrahedral geometry for [Cd(II)] [38,39] in conformity with analytical, conductance and infrared spectral data. Pd(II) complex shows three peaks at 18700 (${}^1\text{A}_{1g} \rightarrow {}^1\text{A}_{2g}$), 21500 (${}^1\text{A}_{1g} \rightarrow {}^1\text{B}_{1g}$) and 24850 cm^{-1} (${}^1\text{A}_{1g} \rightarrow {}^1\text{E}_g$) where these transitions are characteristic of square-planar geometry [40]. Further, the band at 28000 cm^{-1} is due to charge transfer. Further, the $\vartheta_2 / \vartheta_1$ value

observed for the complex is 1.14 which also supports the square-planar geometry [41]. The experimental magnetic moment (μ_{eff}) values for Co(II) and Ni(II) complexes are 4.95, 3.22 B.M. respectively, these values also suggest octahedral arrangement [42-47]. The magnetic moment value of Cu(II) complex is observed at 1.90 B.M, which indicates distorted octahedral geometry [48]. The complexes Zn(II), Cd(II) and Pd(II) are diamagnetic. The ESR studies are performed in order to identify the number of unpaired electrons and the type of bonds between ligand and metal ion of Cu(II) complexes. The EPR parameters are listed in Table 6.4 and Fig. 6.1. The ESR spectrum of Cu(II) complex in solid state was recorded at room temperature and shows two bands, one of small intensity towards low field and another one of large intensity towards high field. Based on these bands, the values of g_{\parallel} and g_{\perp} have been calculated [49]. From the results, $g_{\parallel} = 2.24$ and the other to $g_{\perp} = 2.05$. i.e. $g_{\parallel} > g_{\perp}$, pointing out that metal ion contains an unpaired electron in its $d_{x^2-y^2}$ orbital, and suggests a tetragonal distortion around Cu(II) ions [50]. Kivelson and Neimann [51] showed that $g_{\parallel} > 2.3$ for ionic environment and < 2.3 for covalent compounds. The data presented in Table 6.4 showed that g_{\parallel} obtained for present complex is less than 2.3 indicating the covalent character of M-L band. According to Hathaway and Billing [52], if G value is larger than 4, the exchange interaction is negligible, whereas if its value is less than 4 there is considerable interaction in solid complexes. In the present case, G is found to be greater than 4, thus ruling out solid state exchange interactions between copper centers. Further comparison of K^2_{\parallel} and K^2_{\perp} , the observed K^2_{\parallel} value is (0.603) greater than the value of K^2_{\perp} (0.484) indicate out of plane pi-bonded [33] complex. The spin-orbit coupling constant (λ) was calculated using the relation.

$$g_{\parallel} = [2 - (8 \lambda / 10 Dq)]$$

The λ value for Cu(II) complex which is -499 cm^{-1} was found to be much lower than free ion value λ_0 (-828 cm^{-1}) which also supports covalent character of M-L bond. The ^1H and ^{13}C NMR spectra of the ligand and its metal complexes are shown in Figs 6.2-6.4. In ^1H NMR spectra of the ligand, the carboxylic acid attached to O-H proton showed a signal at 12.93 ppm. In the complexes, the O-H proton showed the signals around 12.82-12.07 ppm. The signal for azomethine CH proton appeared at 8.72 ppm. The signal due to the proton of NH_2 attached to the pyridine ring was observed at 7.38 ppm as a singlet. In the spectra of complexes, the azomethine CH and NH_2 protons

appeared in the range of 8.74-8.61 ppm (CH=N) and 7.33-7.28 ppm (NH₂), respectively. ¹³C NMR spectra of the ligand showed chemical shift values at 167.49, 163.88 and 158.44 ppm due to carboxylic acid (C=O), (C=N) and (C-NH₂), respectively. The aromatic carbons were observed in the range 158.44-112.34 ppm, respectively.

Table 6.2 Infrared absorption frequencies (cm⁻¹) of ligand and its complexes

| Compound | v(N–H) | v(C=N) azomethine | v(C=N) (py) | v(C=O) carboxylic acid | v(M–Cl) | v(M–N) |
|----------|--------|----------------------|----------------|------------------------------|---------|--------|

6.2 DFT Computations

The optimized molecular geometry for the ligand and its metal complexes are shown in Fig. 6.5. The results of bond angles, bond lengths and dihedral angles are

presented in Tables 6.5 and 6.6. On optimization of geometry, the observed global minimum energy of the compounds are -816.95688 Hartree (ANABZA), -2698.19907 Hartree [Co(II)], -2723.30339 Hartree [Ni(II)], -2749.76705 Hartree [Cu(II)], -2779.56640 Hartree [Zn(II)], -1865.00019 Hartree [Pd(II)] and -1904.886800 Hartree [Cd(II)] complexes, respectively.

Molecular electronic properties i.e. electron affinity (A), ionization potential (I), chemical potential (μ), global hardness (η), global electrophilicity power (ω) of ligand and its metal complexes were obtained from frontier molecular orbital energies comprising of HOMO and LUMO.

HOMO and LUMO are known as frontier molecular orbitals. They are important in quantum chemistry, as they determine the molecular reactivity of conjugated systems [53] and the ability of a molecule to absorb electromagnetic radiation. HOMO plays the role of an electron donor, whereas LUMO acts as electron acceptor [54,55] The results are presented in Table 6.7 and illustrated in Fig. 6.6. The complexes under investigation, the frontier molecular orbital energy gap were found in the order ANABZA > Zn(II) > Co(II) > Pd(II) > Ni(II) > Cu(II) > Pd(II). Generally, complexes with a small frontier orbital gap are readily polarizable and normally exhibit high chemical reactivity and low kinetic stability [56-58]. The frontier molecular orbital gap of metal complexes are small compared to the free ligand, hence the complexes are more polarizable than the ligand (Table 6.7). The chemical potential (μ) for the compounds being investigated are -7.31717 [(Co(II)], -6.71403 [(Ni(II))], -5.25906 [(Cu(II)], -6.76342 [(Zn(II)], -4.34001 [(Pd(II)] and -6.18355 [(Cd(II)], complexes respectively, where the negative values indicate the complexes are stable [59].

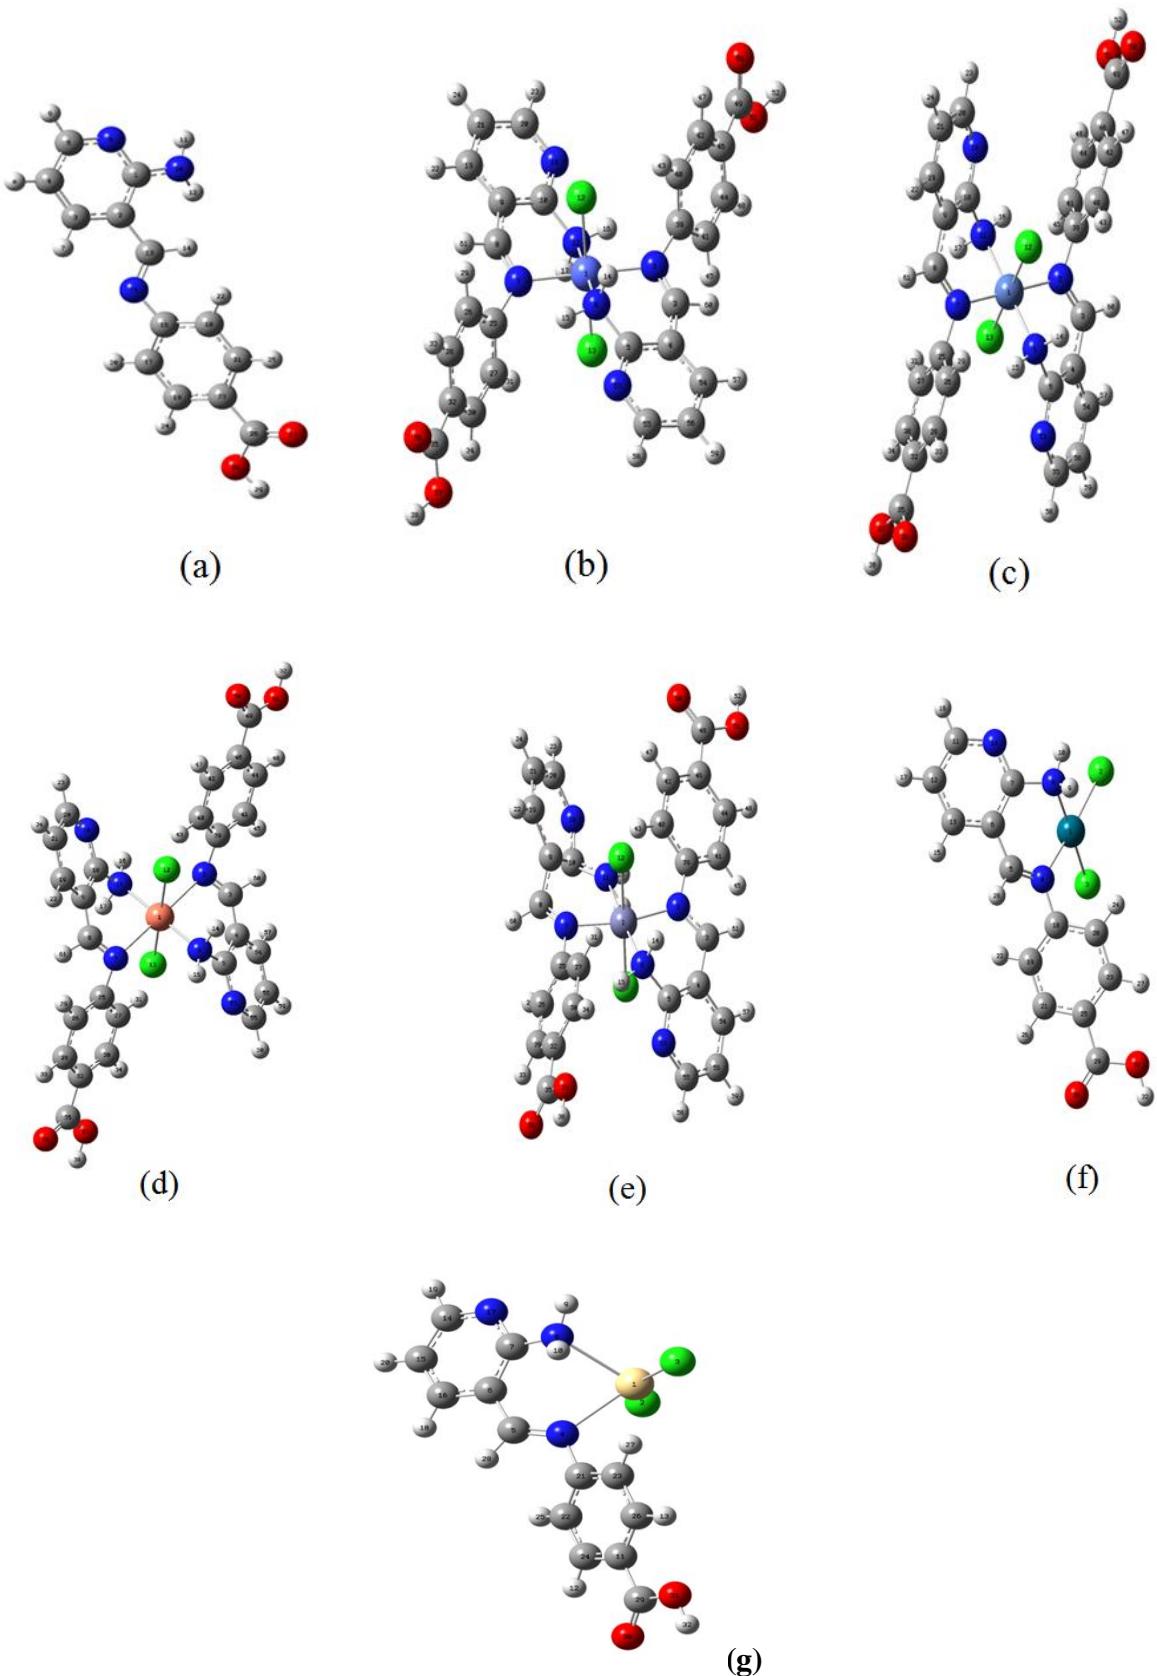

Fig. 6.5 Optimized structures along with atomic numbering of (a) ANABZA (b) Co(II) complex, (c) Ni(II) complex (d) Cu(II) complex, (e) Zn(II) complex, (f) Pd(II) complex and (g) Cd(II) complex.

6.2.1 Non-linear optical (NLO) behaviour

For the most part, density functional theory based approaches are of considerable importance for investigating new non-linear molecular systems [60]. Theoretical approaches have been utilized for determination of polarizability (α_t), hyperpolarizabilities (β_t), total dipole moments (μ_t) and anisotropy of polarizability ($\Delta\alpha$) using density functional theory based on finite field approach and following Buckingham's definitions [61]. This method can reduce the cost and avoid synthesis work for measuring NLO properties. Generally, α_t and β_t were estimated for compounds in the presence of an applied electric field in order to predict cross section of various scattering process, molecular interactions and NLO properties of the system [62,63]. β_t is a third rank tensor hence, it was measured as a $3 \times 3 \times 3$ matrix. From the basis of Kleinman symmetry [64], all the twenty seven components were condensed to ten components indicated as β_{xxx} , β_{xxy} , β_{xyy} , β_{yyy} , β_{xxz} , β_{xyz} , β_{yyz} , β_{xzz} , β_{yzz} , β_{zzz} . So, by using these components X, Y, Z we can calculate the μ_t , α_t and β_{tot} through the following equations.

$$\mu = \mu_x^2 + \mu_y^2 + \mu_z^2 \quad (1)$$

$$\alpha_o = \frac{\alpha_{xx} + \alpha_{yy} + \alpha_{zz}}{3} \quad (2)$$

$$\Delta\alpha = 2^{-1/2}[(\alpha_{xx} - \alpha_{yy})^2 + (\alpha_{yy} - \alpha_{xx})^2 + 6\alpha_{xx}^2]^{1/2} \quad (3)$$

$$\beta = (\beta_x^2 + \beta_y^2 + \beta_z^2)^{1/2} \quad (4)$$

$$\beta_x = \beta_{xxx} + \beta_{xyy} + \beta_{xzz} \quad (5)$$

$$\beta_y = \beta_{yyy} + \beta_{xxy} + \beta_{yzz} \quad (6)$$

$$\beta_z = \beta_{zzz} + \beta_{xxz} + \beta_{yyz} \quad (7)$$

Here, α_t , β_t and μ_t were calculated using DFT approach and the results are given in Table 6.8. It is a usual practice to determine the NLO behavior of compounds by comparing its μ_t and β_t with corresponding values of urea, which are 1.3732 Debye and 0.3728×10^{-30} cm⁵/esu, respectively. The calculated β_t of the ligand is 16.962×10^{-30} cm⁵/e.s.u, which is forty five times greater than urea. Hence, the ligand exhibits NLO properties. The complexes Ni(II), Cu(II) and Zn(II) showed more first order hyperpolarizability values compared to free ligand. The remaining complexes Co(II), Zn(II) and Cd(II) showed lower first order hyperpolarizability values than the ligand. The non-linear optical activity was associated with the intra-molecular charge transfer, obtained from the electron cloud movement, through resonance [65]. Hence, the ligand and its metal complexes Ni(II), Cu(II) and Zn(II) are strong ones for the expansion of NLO materials. The components of first order hyperpolarizability were also helpful to understand charge delocalization in the compounds.

Table 6.8 The values of dipole moment μ (in Debye); polarizability α_t and first order hyperpolarizability β_t (in $10^{-30}\text{cm}^5/\text{e.s.u}$) of ligand and its metal complexes

6.3 Biological evaluations

6.3.1 Antimicrobial screening

Microorganisms used in this work were three gram negative bacteria like *Proteus vulgaris*, *Klebsiella pneumoniae* and *Pseudomonas aeruginosa*, two gram positive bacteria like *Staphylococcus aureus* and *Bacillus subtilis* and fungal strains such as *Aspergillus niger*, *Aspergillus flavus*, *Curvularia lunata*, *Rhizoctonia bataticola* and *Candida albicans* by disc diffusion method [66]. Streptomycin and Ketoconazole were chosen as the reference drugs for bacteria and fungi, respectively. The MIC values of the tested compounds and reference drugs were expressed in $\mu\text{g}/\text{mL}$. The results of antibacterial activity are presented in Table 6.9 and of antifungal activity are listed in Table 6.10. The antibacterial activity results revealed that Cu(II) complex exhibited excellent activity against *S. aureus* and *P. vulgaris* strains (MIC: 4.21 and 8.18 $\mu\text{g}/\text{mL}$, respectively) and it is also showed significant activity against *B. subtilis* (MIC: 5.13 $\mu\text{g}/\text{mL}$) and *P. aeruginosa* (MIC: 6.01 $\mu\text{g}/\text{mL}$). The Pd(II) complex exhibited broad spectrum activity against the strains with MIC values of 5.17 $\mu\text{g}/\text{mL}$ (*S. aureus*), 7.69 $\mu\text{g}/\text{mL}$ (*B. subtilis*), 10.54 $\mu\text{g}/\text{mL}$ (*P. vulgaris*), 7.24 $\mu\text{g}/\text{mL}$ (*K. pneumoniae*) and 7.25 $\mu\text{g}/\text{mL}$ (*P. aeruginosa*), respectively. Moreover, Zn(II) complex against *B. subtilis* (MIC: 11.50 $\mu\text{g}/\text{mL}$), Ni(II) complex against *P. vulgaris* (MIC: 21.01 $\mu\text{g}/\text{mL}$), Cd(II) complex against *B. subtilis* (MIC: 13.89 $\mu\text{g}/\text{mL}$) and Co(II) complex against *P. aeruginosa* (MIC: 10.91 $\mu\text{g}/\text{mL}$) exhibited moderate activity compared to the reference drug. The fungi results showed that Ni(II) and Cu(II) complexes showed potent activity against *A. niger* (MIC = 3.94 $\mu\text{g}/\text{mL}$) and *R. bataticola* (MIC = 6.24 $\mu\text{g}/\text{mL}$), respectively compared to standard Ketoconazole. The Cu(II) and Pd(II) complexes exhibited significant activity against *A. niger* with MIC values of 4.17 and 4.03 $\mu\text{g}/\text{mL}$, respectively. The Co(II), NI(II) and Cu(II) complexes against *C. albicans* showed good activity with MIC values of 7.12, 7.99 and 8.18 $\mu\text{g}/\text{mL}$, respectively. In addition, Ni(II) complex against *A. flavus* (MIC = 10.77 $\mu\text{g}/\text{mL}$) and Zn(II) complex against *C. lunata* (MIC = 6.41 $\mu\text{g}/\text{mL}$) registered moderate activity. The remaining compounds showed poor activity against the tested microorganisms.

Table 6.9 MIC of the synthesized compounds against the growth of bacteria (μM)

| Compound | Minimum Inhibitory Concentration (μg/mL) | | | | |
|-----------------|---|--------------------|--------------------|----------------------|----------------------|
| | <i>S. aureus</i> | <i>B. subtilis</i> | <i>P. vulgaris</i> | <i>K. pneumoniae</i> | <i>P. aeruginosa</i> |

| Ketoconazole | 2.92 | 3.85 | 2.16 | 4.57 | 3.26 |

6.3.2 Antioxidant activity

Antioxidant activity of the synthesized compounds have attracted a lot of interest and has been evaluated mostly in the *in vitro* systems [67,68]. The tested compounds were investigated for their antioxidant ability and these were carried out by using DPPH (1,1-diphenyl-2-picrylhydrazyl) radical as a reagent in the spectrophotometric test.

Ascorbic acid was used as a reference antioxidant. The compounds were performed in triplicate and was then calculated standard deviation [69]. The IC_{50} (μM) values are given in Table 6.11 and Fig. 6.7. It can be seen from the results that Zn(II) complex exhibited significant antioxidant activity with IC_{50} value of $6.11 \pm 0.54 \mu M$ compared to the reference drug which showed IC_{50} value of $4.61 \pm 0.93 \mu M$. The Co(II) complex showed good activity with IC_{50} value of $7.63 \pm 1.57 \mu M$. Ni(II) and Cd(II) complexes exhibited moderate activity with IC_{50} value of $13.16 \pm 0.85 \mu M$ and $17.16 \pm 0.16 \mu M$, respectively. All the other complexes and ligand showed poor activity with IC_{50} values between $20.96 \pm 1.82 \mu M$ to $29.47 \pm 0.18 \mu M$.

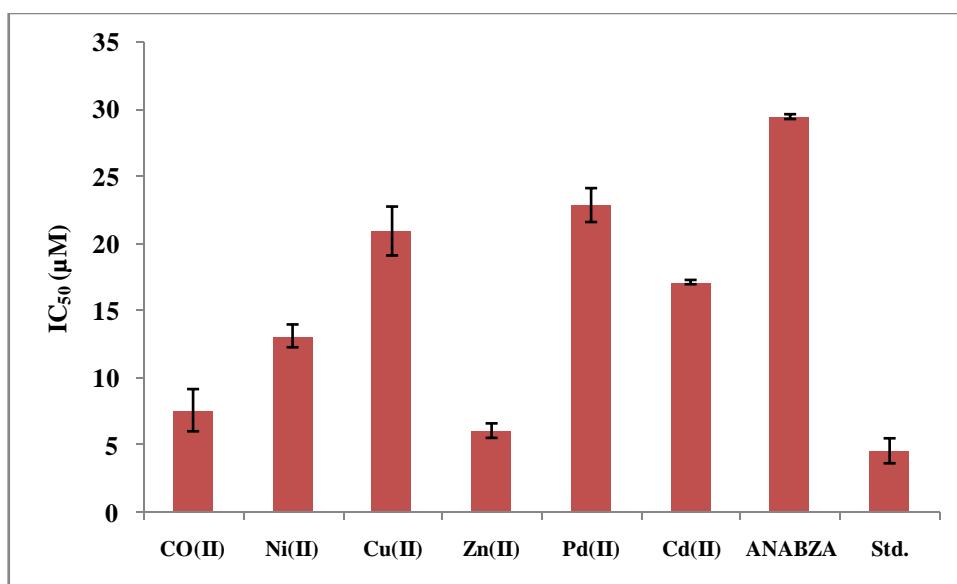

Fig. 6.7 Antioxidant activity of the ligand and its metal complexes.

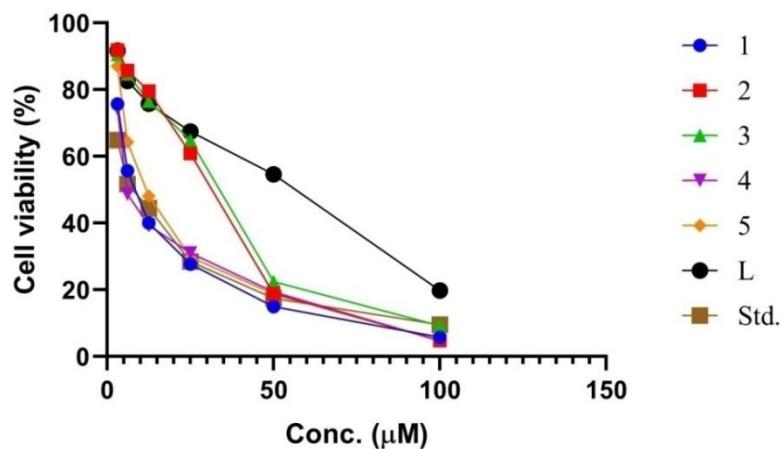

Table 6.11 Antioxidant activity of compounds by DPPH radical scavenging assay

| Compounds | IC ₅₀ (μM) |
|---------------|-----------------------|
| Co(II) | 7.63 ± 1.57 |
| Ni(II) | 13.16 ± 0.85 |
| Cu(II) | 20.96 ± 1.82 |
| Zn(II) | 6.11 ± 0.54 |
| Pd(II) | 22.89 ± 1.26 |
| Cd(II) | 17.16 ± 0.16 |
| ANABZA | 29.47 ± 0.18 |
| Ascorbic acid | 4.61 ± 0.93 |

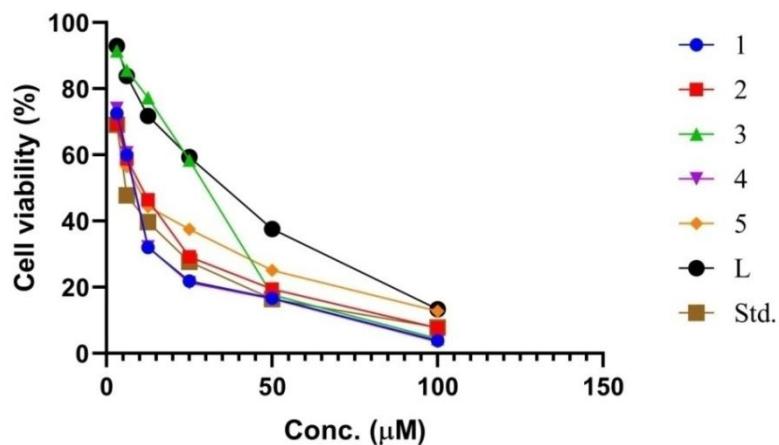

6.3.3 *In vitro* antiproliferative evaluation

Based on the successful evaluations and positive results of the antimicrobial and scavenging activity, it was also decided to examine the anticancer evaluation against different cancer cell lines, IMR-32 (neuroblastoma), HeLa (cervical), MCF-7 (breast), A549 (lung), HepG-2 (liver) and HEK293 (embryonic kidney) by using 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) method. The MTT assay results are shown in IC₅₀, and expressed in micromolar units and were summarized in Table 6.12. The percentage of cell viability *versus* concentration graphs are shown in Fig. 6.9. Cisplatin was used as reference drug. The results clearly indicate that Zn(II) complex showed excellent anti-proliferative activity against IMR-32, A549 and HepG-2 with IC₅₀ value of 7.81 ± 0.52 μM, 6.18 ± 1.15 μM and 15.28 ± 1.26 μM, respectively. The values are close to standard cisplatin (IC₅₀ = 5.78 ± 0.12 μM, 4.90 ± 0.31 μM and 10.52 ± 0.40 μM, respectively) and they showed good activity against MCF-7 (IC₅₀ = 7.41 ± 0.32 μM) and HeLa (IC₅₀ = 5.99 ± 0.23 μM). Similarly Co(II) complex was potent with a broad spectrum activity with IC₅₀ values against HeLa (5.94 ± 1.13 μM), IMR-32 (8.51 ± 0.12 μM), HepG-2 (16.51 ± 1.18 μM), A549 (8.27 ± 0.38 μM) and MCF-7 (13.26 ± 0.19 μM). The observed higher efficiency of Co(II) and Zn(II) complexes are due to the presence of ligand coordinated to central cobalt and zinc metal ions. Also Ni(II) complex against HeLa (IC₅₀ = 12.72 ± 0.27 μM) and ANABZA against A549 (IC₅₀ = 19.38 ± 1.07 μM)

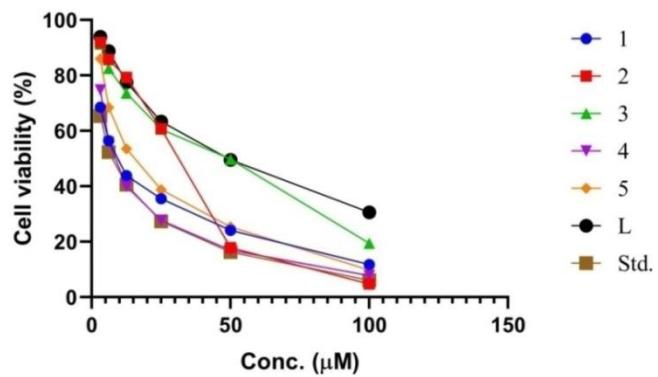

exhibited moderate activity. The other compounds exhibited least activity against the cell lines. In addition, we have also tested the cytotoxicity of Co(II) and Zn(II) complexes against HEK293 with IC_{50} values of $96.57 \pm 0.42 \mu\text{M}$ and $81.37 \pm 0.10 \mu\text{M}$, respectively. None of the potent complexes [Co(II) and Zn(II)] interrupted the viability of the normal cell line, suggesting that the potent complexes are not toxic.

Values are expressed in mean ± SD of three replicates. ND stands for not determine

6.3.4 Molecular docking

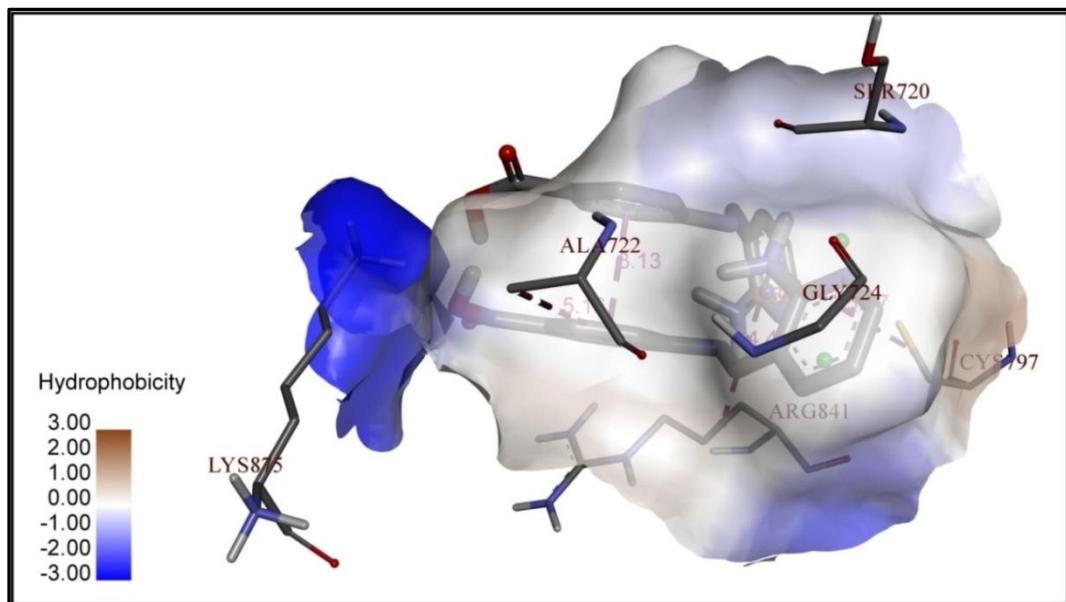

The *in silico* molecular docking analysis of the ligand and its metal complexes against human epidermal growth receptor (HER2) and epidermal growth factor (EGFR) was carried out to verify the relation between *in vitro* antiproliferative activity results and binding affinities of the inhibitors using auto dock programme. It plays a major role in the malignant growth from various origins [70]. It is expressed on the surfaces of most of the cell of human body [70] The over expression of HER2 involved in several cancers like breast cancer, adenocarcinoma of lungs, stomach cancer [71], ovarian cancer [72] and uterine cancer [71,72]. It is a suitable target for kinase inhibitors [70] on the other hand, EGFR is a prominent cell-surface receptor which belongs to the EGFR family [73]. The TKD (tyrosine kinase domain) and extracellular mutations of EGFR causes non small cell lung cancer and glioblastoma, respectively [74-76]. Its over expression also leads to epithelial tumors of the head, neck and anal cancer [77,78]. By considering the aforementioned reasons, we have chosen target protein receptors HER2 and EGFR for docking studies. Herein, the main aim is to explore the binding behaviour (in terms of binding energy) of the target compounds against HER2 and EGFR and their results are compared with well established inhibitors (*in vitro* and *in vivo*) such as Canertinib (HER2), Afatinib (HER2), Lapatinib (EGFR) and Gefitinib (EGFR) [79]. The comparative docking studies of the compounds and the reported inhibitors (Canertinib,

Afatinib, Lapatinib and Gefitinib) against proteins HER2 and EGFR along with their corresponding binding energies are listed in Table. 6.13. As shown in table 6.13, docking results revealed that Co(II) and Zn(II) complexes showed the least binding energies compared to other metal complexes against receptors HER2 and EGFR with their binding energies of -7.31 and -6.46 kcal/mol (for Co(II) complex); -8.02 and -7.35 kcal/mol (for Zn(II) complex), respectively. Hence HER2 and EGFR were taken as the target protein receptors for insightful discussion on Co(II) and Zn(II) complexes. The molecular docking results for Co(II) complex against HER2 exhibited four hydrogen bonds; one strong hydrogen bond between OH group of carboxylic acid moiety and the amino acid residue LYS875 with bond length 1.80 Å, one hydrogen bond between amino group of 2-aminopyridyl ring and amino acid residue SER720 with bond length 2.28 Å, one hydrogen bond between OH group of benzoic acid moiety and the amino acid residue ALA722 with bond length 2.90 Å and one carbon-hydrogen bond between -CH group of pyridyl ring and amino acid residue GLY724 with bond length 3.03 Å. The pyridyl ring interacts with amino acid residues ARG841 and CYS797 and the phenyl ring of the benzoic acid moiety interacts with amino acid residue ALA722 through hydrophobic interactions. In the related Co(II) complex against EGFR it exhibited eight hydrogen bonds; one strong hydrogen bond between -O- atom of carboxylic acid moiety and the amino acid residues ARG817 and GLY697 with bond length 1.87 Å and 3.28 Å respectively, one hydrogen bond between H-atom of the carboxylic acid moiety and amino acid residue ASP813 with bond length 2.14 Å, one hydrogen bond between carbonyl oxygen atom of the carboxylic acid group and the amino acid residue LYS721 with hydrogen bond length 3.04 Å, one hydrogen bond between amino group of 2-aminopyridyl ring and amino acid residue ARG817 with bond length 2.08 Å, one hydrogen bond between N-atom of pyridyl ring and the amino acid residue CYS773 with bond length 2.87 Å and one carbon-hydrogen bond between -CH group of pyridyl ring and amino acid residue ASP831 with bond length 3.16 Å, one hydrogen bond between N-atom of the imine group and the amino acid residue ARG817. The pyridyl ring interacts with the amino acid residues LEU820, ARG817 and VAL702 and the phenyl ring of the benzoic acid moiety interact with amino acid residue ARG817 through hydrophobic interactions. The hydrogen bonding interactions and hydrophobic interactions of the Co(II) complex are shown in Fig.s 6.9 and 6.10.

Zn(II) complex against HER2 exhibited five hydrogen bonds; one strong hydrogen bond between the –OH group of benzoic acid moiety and amino acid residue PRO877 with bond length 1.69 Å, one strong hydrogen bond between the –OH group of benzoic acid moiety and amino acid residue ASP837 with bond length 1.85 Å, one hydrogen bond between –CH group of imine moiety with amino acid residue ALA722 with bond length 3.56 Å, one hydrogen bond between –CH group of pyridyl moiety with amino acid residue GLY719 with bond length 3.69 Å and one hydrogen bond between carbonyl group of benzoic moiety with amino acid residue PRO877 with bond length 3.77 Å. The pyridyl ring interacts with the amino acid residues ARG841, LYS745 and VAL726 through hydrophobic interactions. In addition to this there was an electrostatic interaction between the pyridyl moiety with amino acid residues ASP855 and CYS797. In the related Zn(II) complex against EGFR it exhibited eight hydrogen bonds; three hydrogen bonds between carbonyl oxygen atom of the carboxylic acid group and the amino acid residue ARG779, LYS851 and LYS889 with hydrogen bond lengths 1.93 Å, 1.95 Å and 3.37 Å, respectively, one strong hydrogen bond between the –OH group of benzoic acid moiety and amino acid residue LYS889 with bond length 2.98 Å, two hydrogen bonds between amino group of 2-aminopyridyl ring and amino acid residue SER696 with bond length 1.61 Å, and 1.92 Å, one hydrogen bond between N-atom of pyridyl ring with amino acid residue GLY695 with bond length 3.57 Å and one Pi-donor hydrogen bond between pyridyl ring and amino acid residue SER696 with bond length 2.97 Å. The pyridyl ring interacts with the amino acid residues ARG817 through hydrophobic interactions. The hydrophobic interactions also played a vital role in increasing the affinity between the synthesized compounds and targeted proteins. The hydrogen bonding interactions and hydrophobic interactions of the Zn(II) complex are shown in Fig.s 6.15 and 6.16. Finally, the docking results clearly suggest that the affinity of the synthesized compounds towards the protein receptor HER2 is better than that of the protein receptor EGFR. The docking results were quite consistent with experimental anticancer activity. The best docking poses of the remaining complexes [Ni(II), Cu(II), Pd(II) and Cd(II)] against the proteins HER2 and EGFR are shown in Fig.s 11-20.

6.4 Conclusions

In summary, the complexes with Schiff base ligand have been designed, synthesized and characterized, with an aim to evaluate them for antioxidant, antimicrobial, cytotoxic activity, DFT calculations and HER2, EGFR target based *in silico* docking studies. The metal-ligand stoichiometry in the complexes of Co(II), Ni(II), Cu(II) and Zn(II) corresponds to 1:2, whereas in case of Pd(II) and Cd(II), 1:1 stoichiometry was observed, wherein the ligand behaves in a bidentate manner towards metals coordinating through azomethine nitrogen atom and the nitrogen of amine group. Based on DFT and spectral studies, octahedral geometry is assigned for Co(II), Ni(II) and Zn(II) complexes, distorted octahedral for Cu(II) complex, tetrahedral for Cd(II) and square-planar geometry for Pd(II) complex. All the complexes are non-electrolytic in nature in DMF. The evaluation of ESR parameters from the ESR spectrum confirms that the M-L bonds are covalent and out of plane π -bonded. From the antimicrobial activity results, it is known that metal complexes have better effect compared to the free ligand indicating that the metals are actually in action. Specifically, Cu(II) complex has shown excellent antimicrobial activity; likewise, Pd(II) complex exhibited a broad spectrum of antibacterial activity, and Ni(II) complex has shown superior antifungal activity compared to Streptomycin and Ketoconazole. Zn(II) complex has shown good antioxidant activity compared to reference drug ascorbic acid. In addition, complexes of Zn(II) and Co(II) have shown potent anti-proliferative activity against IMR-32 ($IC_{50} = 7.81 \pm 0.52$, 8.51 ± 0.12 μ M), A549 ($IC_{50} = 6.18 \pm 1.15$, 8.27 ± 0.38 μ M) and HepG-2 ($IC_{50} = 15.28 \pm 1.26$ μ M, 16.51 ± 1.18 μ M), respectively. The docking results revealed that complexes Co(II) and Zn(II) exhibited the least binding energies against receptors HER2 and EGFR with their binding energies -7.31 and -6.46 kcal/mol (for Co(II) complex); -8.02 and -7.35 kcal/mol (for Zn(II) complex), respectively compared to Canertinib (HER2), Afatinib (HER2), Lapatinib (EGFR) and Gefitinib (EGFR). From the results, it is clear that the complexes are strongly bound to HER2 and EGFR protein receptors. Interestingly, these compounds have shown most potent anticancer activity and minimum binding energies obtained by docking study. The results indicate that *in silico* molecular docking studies correlated well with the experimental anti-proliferative activity results.

BRIEF CURRICULUM VITAE

Mr. Konakanchi Ramaiah was born on 12th June 1989 in Gunjaloor, Suryapet, India. He did B.Sc. Chemistry in Osmania University (OU), Hyderabad and M.Sc. Inorganic Chemistry in Kakatiya University (KU) campus, Warangal, India. After completing her post-graduation, he has joined as a research scholar under the guidance of Dr. K. Laxma Reddy, Professor, Department of Chemistry, National Institute of Technology, Warangal in June 2014.
