**DEPARTMENT OF ELECTRICAL ENGINEERING  
NATIONAL INSTITUTE OF TECHNOLOGY WARANGAL**

**CERTIFICATE**

This is to certify that the thesis entitled "**Investigation of Impact of Generation Uncertainty on Optimal Power Flow Using New Hybrid Multi-Objective Evolutionary Algorithms**", which is being submitted by **Mr. Avvari Ravi Kumar, Roll No: 718122**, is a bonafide work submitted to National Institute of Technology Warangal in partial fulfillment of the requirements for the award of the degree of **Doctor of Philosophy** in Electrical Engineering. To the best of my knowledge, the work incorporated in this thesis has not been submitted elsewhere for the award of any degree.

Date: 21 December, 2022  
Place: Hanumakonda

**Dr. D. M. Vinod Kumar**  
(Thesis Supervisor)  
Professor (HAG)

Department of Electrical Engineering  
National Institute of Technology Warangal  
Hanumakonda –506004, India.

## **DECLARATION**

This is to certify that the work presented in the thesis entitled "**Investigation of Impact of Generation Uncertainty on Optimal Power Flow Using New Hybrid Multi-Objective Evolutionary Algorithms**", is bonafide work done by me under the supervision of Dr. D.M.Vinod Kumar, Professor (HAG), Department of Electrical Engineering, National Institute of Technology Warangal, India and was not submitted elsewhere for the award of any degree.

I declare that this written submission represents my ideas in my own words and where others' ideas or words have been included; I have adequately cited and referenced the sources. I also declare that I have adhered to all principles of academic honesty and integrity and have not misrepresented or fabricated or falsified any idea/date/fact/source in my submission. I understand that any violation of the above will be a cause for disciplinary action by the institute and can also evoke penal action from the sources which have thus not been properly cited or from whom proper permission has not been taken when needed.

Date: 21 December, 2022  
Place: Hanumakonda

**Avvari Ravi Kumar**  
(Roll No: 718122)

*I would like to dedicate my thesis to my parents:*

*Late Sri Avvari Ramanaiah*

*Late Smt. Avvari Mahalakshmamma*

## ACKNOWLEDGEMENTS

I am glad to express my deep sense of gratitude and thanks to my supervisor **Dr. D.M. Vinod Kumar**, Professor (HAG), Department of Electrical Engineering, National Institute of Technology Warangal, for his continuous support, guidance, and valuable suggestions. I am grateful to him for having faith in me throughout my Ph.D. His knowledge, expertise, and experience helped me to perform extensive research.

I am very much thankful to **Dr. S. Srinivasa Rao**, Chairman of the Doctoral Scrutiny Committee, and Professor, Department of Electrical Engineering for his continuous support, encouragement, and suggestions.

I am very thankful to **Dr. B. L. Narasimharaju**, Professor & Head, Department of Electrical Engineering for his continuous support, encouragement, and suggestions.

I take this privilege to thank my Doctoral Scrutiny Committee members, **Dr. Ch. Venkaiah**, Professor, Department of Electrical Engineering, **Dr. A.V.Giridhar**, Associate Professor, Department of Electrical Engineering, **Dr. P. Muthu**, Associate Professor, Department of Mathematics, for their detailed review, constructive suggestions, and excellent advice during the process of this research work. I would like to thank **Dr. M. Raja Vishwanathan**, Associate Professor, Department of Humanities and Social Science for his valuable suggestions, continuous support, and cooperation.

I would like to thank the teaching, and non-teaching members, and fraternity of the Department of Electrical Engineering of NIT Warangal for their support and encouragement.

I wish to express my sincere thanks to **Prof. N. V. Ramana Rao**, Director, NIT Warangal for his support and encouragement.

I would like to take this opportunity to thank my seniors Dr. S. Kayalvizhi, Dr. Kiran Teeparthi, Dr. C. Bhanu Prasad, and fellow scholar Mr. T. Vinod Kumar for their support and encouragement.

I would like to thank all my teachers, colleagues, and seniors at various places for their support and encouragement.

I would like to thank my wife **Mrs. Lavanya** for being a constant source of inspiration and support. I take this opportunity to thank all my family members and my well-wishers for their understanding, support, and encouragement during this research work. I would like to thank all those who helped me directly and indirectly at various stages of this work.

**Avvari Ravi Kumar**

## ABSTRACT

In general, optimization promotes the economical and efficient operation of electrical systems. The majority of power system issues are often non-linear, non-convex, and involve the simultaneous optimization of multiple contrasting objective functions. Optimization approaches may be required to address a variety of continuous and discrete variables in the problems. In the past, classical/traditional/conventional optimization approaches were employed. Conventional techniques typically use gradient-based searches that converge to local optimal solutions, and it was known that they performed well for convex and continuous optimization problems. Later, a transformation in optimization methods initiated Evolutionary Algorithms (EAs) into the picture. The majority of these techniques can effectively circumvent the issue of premature convergence and explore the search area toward the global optimal solution. In addition, renewable energy sources (RESs) have become a vital part of the modern power system. Due to the uncertainty and unpredictability of RESs, the formulation of the power system problem has grown complex and dynamic. The main purpose of this research is to implement cutting-edge variations of decomposition-based MOEA (MOEA/D) for the OPF problems in power systems. Moreover, operational and security limitations are prevalent in electrical networks. The static penalty method was the simplest and most easy strategy for addressing power system limits. In this thesis, a new constraint handling method (CHM) referred to as the superiority of feasible solutions (SF) method in addition to the penalty method was introduced. In conjunction with MOEAs, CHM has been effectively used to previously known and freshly formulated constrained optimization issues in the power system, notably the OPF problem.

The following are the thesis contributions:

- A novel hybrid MOEA based on decomposition and local dominance was proposed for the OPF problem. The MOOPF aims to minimize total generation cost, emission, active power loss, and voltage magnitude deviation. To address the limitations of the MOOPF problem, a penalty function method was implemented. In addition, a fuzzy technique was used to determine the optimal values among Pareto-optimal alternatives. The proposed strategy combines the decomposition and local dominance strategies to promote convergence by enhancing diversity.
- A new hybrid decomposition and summation of normalized objectives with improved diversified selection-based MOEA including wind energy conversion system (WECS)

and solar photo-voltaic system (SPVS) uncertainty for OPF was carried out. This chapter recommends a novel CHM, that adaptively inserts penalty and avoids the parameter relying on penalty calculation. In the OPF cost study, the influence of RES such as WECS and SPVS integration was examined. To minimize the total generation cost, the cost of RESs is factored into the OPF issue to examine the influence of intermittent and unpredictable renewable sources on cost and operation. Weibull and Lognormal PDFs are applied to characterize the unpredictability of WECS and SPVS respectively.

- A new hybrid decomposition and summation of normalized objectives with improved diversified selection-based MOEA including WECS, SPVS, and plug-in electric vehicle system (PEVS) uncertainty for the OPF problem were done. The MOOPF problem was solved using a unique CHM that adaptively inserts the penalty and avoids the parameter relying on penalty calculation. In addition, a fuzzy technique was used to determine the optimal values among Pareto-optimal alternatives. The impact of intermittence of WECS, SPVS, and PEV integration was considered for optimal cost analysis.
- A new hybrid decomposition and invasive weed optimization (IWO) based MOEA including WECS, SPVS, and PEV uncertainty was presented for the OPF problem. The standard OPF problem was transformed into a stochastic OPF by incorporating the uncertainty of WECS, SPVS, and PEVSs. The MOOPF problem was solved using a unique CHM that adaptively inserts the penalty and avoids the parameter relying on penalty calculation. In addition, a fuzzy technique was used to determine the optimal values among Pareto-optimal alternatives. The impact of intermittence of WECS, SPVS, and PEV integration was considered for optimal cost analysis.

## Introduction

### 1.1 Optimal Power Flow Overview

The OPF has become a popular topic of discussion amongst power system academics all over the world due to the interesting variety of issues it raises. The OPF is presented as a single or multi-objective issue to minimize total generating cost, emission, active power loss, voltage magnitude deviation, etc., subject to restrictions on the generator's capability, the line's capacity, the bus voltage, and the balance of power flow. The OPF program provides the ideal values for the decision variables, resulting in the efficient and economic operation of the power system. Main control variables refer to the network's generator bus real power, reactive power, and bus voltages. The latter regulates the flow of reactive power, which is often balanced by connecting capacitors with the proper ratings to the network that supplies inductive loads. The bus voltages and complex powers in the lines obtained throughout the optimization indicate the optimum operating condition, which may result in the fulfillment of one or more network objectives. Therefore, OPF, which requires complex computations with various parameters and the identification of optimal solutions while simultaneously fulfilling all restrictions, remains the most challenging problem to solve.

In recent days, issues such as the rise in penetration of renewable sources and the rise in load demand are posing new challenges to the modern power system. The OPF is a technique for power system planning to find the best operating point in terms of real power generation, voltage magnitude, tap settings of transformers, and compensators to optimize the specific objective function(s). The OPF is a nonlinear optimization issue with continuous and discontinuous control variables. However, discrete control variables like transformer tap settings, shunt devices, and phase shifters make the OPF problem highly complicated.

In recent times, RESs penetration has increased drastically in power systems. The penetration of RESs has introduced many challenges to the power system. The intermittent nature of RESs makes the system highly complex in terms of operation and control. The uncertain nature of RESs is required to be modeled accurately to examine the dynamic functioning of the power system. Due to its unpredictable nature, protection schemes need to be updated for operating the power system in a secure region. In a power system, the main aim is to operate it with optimal cost and simultaneously satisfy the operating and security constraints. The OPF determines the optimal control settings satisfying system constraints and

security constraints to operate economically. OPF is an optimizing tool for power system operation analysis, scheduling, and energy management applications.

## 1.2 Mathematical Representation

The OPF is a non-linear, non-convex optimization problem that aims to minimize a given objective function under a variety of equality and inequality restrictions. The OPF model is formulated as follows:

$$\text{Minimize: } f(x, u) \quad (1.1)$$

$$\text{subject to : } \begin{cases} g(x, u) = 0 \\ h(x, u) \leq 0 \end{cases}$$

Where  $f(x, u)$  is the objective function,  $x$  and  $u$  are the vector of state and control variables respectively,  $g(x, u)$  and  $h(x, u)$  are the collection of equality and inequality restrictions respectively.

### a) State variables

The state variables for the power system can be written as follows in the vector  $x$ :

$$x = [P_{G1}, V_{L1}, \dots V_{LNl}, Q_{G1}, \dots Q_{GNG}, S_{l1}, \dots S_{lnl}] \quad (1.2)$$

Where,  $NL$  and  $nl$  denote the number of load buses and lines respectively.  $P_{G1}$  is the slack bus real power,  $Q_{Gi}$  is the  $i$ -th generator bus reactive power,  $V_{Li}$  denotes  $i$ -th load bus voltage and  $S_{li}$  is the  $i$ -th line loading.

### b) Control variables

The decision variables for the power system can be written as follows in the vector  $u$ :

$$u = [P_{G2}, \dots P_{GNG}, V_{G1}, \dots V_{GNG}, T_1, \dots T_{NT}, Q_{C1}, \dots Q_{CNC}] \quad (1.3)$$

Where  $NG$ ,  $NT$  and  $NC$  are the number of generators, transformers and shunt compensators respectively.  $P_{Gi}$  is the  $i$ -th generator bus real power (except slack bus).  $V_{Gi}$  is the  $i$ -th generator bus voltage magnitude,  $T_i$  is the  $i$ -th transformer tap ratio,  $Q_{Ci}$  is the  $i$ -th bus shunt compensator.

In general, a problem having more than one objective is treated as a multi-objective optimization problem (MOP). While formulating the MOP, the objective functions are chosen such that they conflict with each other. The conflict between objectives depends on the correlation among the objectives. Different objectives will have different degrees of correlation among a combination of objectives. To formulate the combination of objectives, four different objectives are considered in this thesis, which are minimization of (a) total generation cost ( $J_1$ ), (b) emission ( $J_2$ ), (c) active power loss ( $J_3$ ), and (d) voltage magnitude deviation ( $J_4$ ). To show the change in trade-off solutions with an increase in objectives, the multi-objective problems were designed with two objectives, three objectives, and four objectives. These multi-objectives were formulated from the combination of four objectives. The combination of

objectives were taken into account to test the MOP with different degrees of correlation among the objectives.

### 1.3 Best-Compromised Solution (BCS)

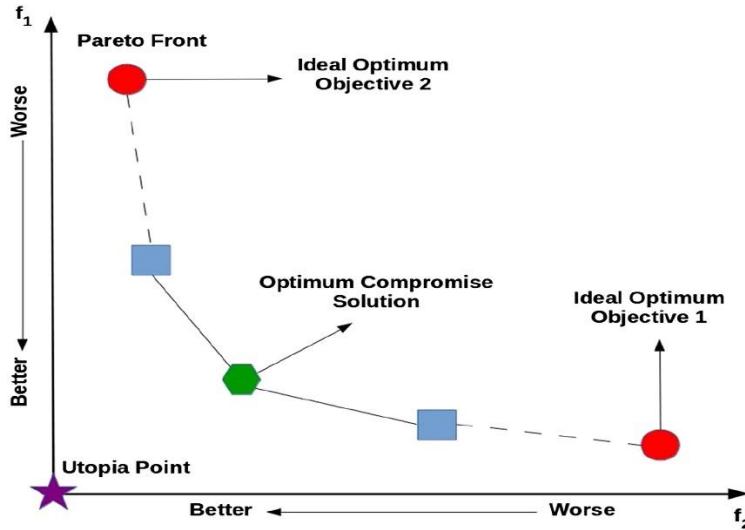

The fuzzy method [12] was employed to obtain the BCS from a set of non-dominated solutions of the Pareto optimal front. The membership value ( $\mu_m^k$ ) of every objective is computed as follows:

$$\mu_m^k = \begin{cases} 1; & \text{for } F_m^k \leq F_m^{\min} \\ \frac{F_m^{\max} - F_m^k}{F_m^{\max} - F_m^{\min}} & ; \text{for } F_m^{\min} \leq F_m^k \leq F_m^{\max} \\ 0; & \text{for } F_m^k \geq F_m^{\max} \end{cases} \quad (1.4)$$

where  $F_m^{\min}$ , and  $F_m^{\max}$  are the limits on fitness values for the objective  $m$  out of all the non-dominated solutions;  $F_m^k$  is the fitness value of objective  $m$  for non-dominated solution  $k$ . The normalized membership value ( $\mu^k$ ) for every non-dominant solution is determined as follows:

$$\mu^k = \frac{\sum_{m=1}^M \mu_m^k}{\sum_{k=1}^{N_d} \sum_{m=1}^M \mu_m^k} \quad (1.5)$$

where  $N_d$  and  $M$  indicate the number of non-dominated solutions and objective functions respectively. The optimal trade-off is represented as the solution with the highest  $\mu^k$  value.

**Fig.1.1.** Pictorial representation of Pareto-optimal solutions.

### 1.4 Evolutionary Optimization Algorithms

The limitation of conventional optimization methods can be overcome with alternative optimization techniques such as evolutionary optimization techniques, which can handle nonlinear, non-differentiable, real-world complex problems, highly constrained, high dimensionality problems, and discrete optimization problems. Evolutionary optimization algorithms are one of the branches of meta-heuristic optimization methods, which are inspired

by the biological evolutionary theory to solve optimization problems. The evolutionary algorithms can be classified into two categories: i) population-based and ii) trajectory-based algorithms. Population-based algorithms are inspired by the biology and swarms of different species. In population-based algorithms, multiple solutions are propagated to find the optimal solution in the decision space. genetic algorithm (GA), particle swarm optimization (PSO), etc., are examples of population-based algorithms. Trajectory-based algorithms are adapted from physics, in which a single solution is propagated to find the optimal solution. Tabu search, simulated annealing, etc., are examples of trajectory-based algorithms. Evolutionary optimization algorithms are best suited to resolve the OPF issue. The OPF can be structured as both single-objective and multiple-objective issues. In practical applications of power systems, one needs to consider multiple objectives rather than a single objective. The multi-objective formulation gives the trade-off solutions which are useful in making the decision of power system planning studies.

### 1.5 Multi-Objective Evolutionary Algorithms (MOEAs)

The OPF problem can be solved using MOEA. The optimization process provides the best feasible value which is the maximum or minimum value of a given objective. In general, multi-objective optimization is expressed as follows:

$$\begin{aligned} & \text{minimize } F(x) = (f_1(x), f_2(x), \dots, f_m(x))^T \\ & \text{subjected to constraints} \end{aligned} \quad (1.6)$$

Where  $F(x)$  is the multi-objective function formulated from ‘ $m$ ’ individual objectives  $f(x)$ .

When  $m \geq 2$ , the optimization is referred to as multi-objective optimization problem (MOP).

The MOEAs are divided into four categories: i) Pareto dominance based, ii) Decomposition based, iii) Indicator based, and iv) Model-based.

- i. **Pareto dominance-based MOEA:** The individuals are ordered based on their Pareto dominance using the non-dominated sorting method, which increases the convergence of MOEA, and the crowding distance is used to increase the diversity of solutions on the Pareto front.
- ii. **Decomposition-based MOEA:** The MOP is transformed into several single objective optimization problems. The algorithm divides the problem into subproblems using scalarization methods based on weights. Based on the distance between aggregation weights, neighborhoods are generated. The subproblem is simultaneously solved by exchanging information among the neighboring solutions. This improves the efficiency of searching the objective space for optimal solutions.

- iii. **Indicator-based MOEA:** These methods use performance indicators to guide the search process and the solutions are selected based on performance indicator value. Several types of indicator metrics are available in the literature such as hypervolume indicator, R2 indicator, inverted generational distance (IGD), and so on.
- iv. **Model-based MOEA:** The model-based MOEAs add the ability to learn from the environment in evolutionary algorithms. Traditional MOEAs such as Pareto, decomposition, and indicator-based are intended to operate on fixed heuristic strategies such as reproduction, selection, and variation. In the process of searching for a feasible solution, traditional MOEAs may not interact with the rapidly changing environment due to the complex properties of the problem to be solved. The model-based MOEAs uses machine learning techniques to adapt to environmental changes in the evolutionary process. The model-based MOEA replaces the traditional heuristic operators such as selection, reproduction, and fitness evaluation with a machine learning model. The models use the candidate solutions as sample training data from the current generation to generate the best solutions by learning the changes in the environment.

In all evolutionary algorithms, maintaining a proper balance between exploitation and exploration is necessary to get the global optimum solution. Exploration is the process of searching broadly in objective space, whereas exploitation is the local searching done in the vicinity of an optimal or nearly ideal solution. Excessive exploitation results in the algorithm being stopped at a local optimum point rather than getting close to the global optimum solution, whereas exhaustive exploration lengthens the convergence time. Therefore, while building evolutionary algorithms, striking the right balance between exploitation (local search) and exploration (global search) is crucial.

The MOEAs are normally modeled to handle different conflicting goals, such as maximizing the spread of solutions along the Pareto front (i.e., diversity) and minimizing the distance between the solutions along the Pareto front (i.e., convergence) [23]. The trade-off between convergence and diversity is important to choose the best solution among the solutions obtained. Therefore, to attain a balance between exploration and exploitation in this thesis, a new hybrid MOEAs were proposed.

### **Literature Review**

## Chapter 2

### Literature Review

#### 2.1 Overview

In recent years, the penetration of RESs has increased rapidly in the power system, which in turn has led to many challenges to monitor and operate the modern power system. The OPF is a technique in power system planning to find the best operating point in terms of real power generation, voltage magnitude, off-nominal transformer tap positions, and shunt compensator to optimize the specific objective function(s) [1]. The OPF is a non-linear, and non-convex optimization problem that includes both continuous and discrete control variables. A discrete control variable like transformer tap setting, shunt device, and phase shifter makes the OPF problem complex. Moreover, the uncertainty and unpredictability of renewable energy sources make the system highly complex to operate and control [1]. The uncertain nature of RESs is required to be modeled accurately to monitor and control the dynamic behavior of the power system network more reliably and operate more efficiently. The OPF determines the optimal control variables by meeting the system constraints. A significant amount of research has been carried out in the OPF using both deterministic and stochastic methods.

Several deterministic methods have been offered in the literature to resolve PF problems. It includes linear programming (LP), non-linear programming (NLP), etc. Lobato *et. al.* [2] presented LP-based OPF for power loss reduction and reactive power margin minimization of generators. Yan *et. al.* [3] proposed the predictor-corrector interior-point method for the OPF problem in the form of a rectangle. During optimization, the Hessian matrices were computed only once and treated as constant. In [4], the authors proposed a quadratic programming method to minimize power loss in the OPF problem. The gradient method was proposed in [5] to develop the dynamic OPF to include wind farms without considering the cost of wind power. For solving the OPF model including wind plant, authors [6] used the Newton method and interior-point methods. However, conventional or deterministic optimization method may not handle mixed variable optimization problems; it requires mathematically well-defined objective functions and constraints, are sensitive to initial values of the problem, are problem-specific, exhibits poor convergence characteristics, and the theoretical assumptions related to problems that lead to solutions stuck at local optima points. Moreover, these methods are unable to solve real-world optimization issues. Likewise, several authors have attempted the OPF as a single-objective optimization approach with conventional optimization methods [7, 8]. To overcome the limitations of classical or deterministic

techniques, various population-based EAs were developed, which can handle nonlinear, non-differentiable, real-world complex problems, highly constrained, and high dimensionality problems, and discrete optimization problems.

The stochastic search approach adopted by EAs may explore the search area for global optimality effectively. Genetic algorithm [9], Evolutionary programming [10], and others were among the initial attempts to apply stochastic population-based techniques for OPF. Duman *et. al.* [11], the symbiotic organisms search (SOS) algorithm was proposed to solve security-constrained AC-DC OPF including wind, PV, and PEV sources. Sarda *et. al.* [12], proposed a robust CE-CMAES for solving the dynamic OPF problems. In this work, the dynamic OPF problem was modeled by including the wind, PV, and PEV uncertainties. In [13], the authors proposed an SOS method for resolving the AC OPF problem with thermal-wind-solar-tidal systems. The uncertainties associated with wind, PV, and tidal energy systems were modeled with Weibull, Lognormal, and Gumbel PDFs respectively. In [14], the authors developed and solved different constrained OPF problems for power systems containing RESs like wind and solar power using an HMICA-SQP. Biswas *et. al.* [15], used the SHADE algorithm with the SF method for arriving at the solution to OPF with RESs. Similarly, in [16, 17] the authors proposed several meta-heuristic optimization methods for solving OPF with RESs. However, these were formulated as single-objective optimization problems. In the real world, the OPF problem is multi-objective and the tradeoff between multiple objects gives better optimal conditions for operation. In most practical optimization problems, the objective functions conflict mutually. According to the no free lunch (NFL) theorem [18], no single solution is available which can optimize all the objectives. To overcome this problem, MOPs have been developed and widely exist in all applications, such as cloud computing, path planning, design, and scheduling [19]. These problems consist of more than one conflicting objective.

In contrast to the majority of single-objective examples addressed in the aforementioned OPF literature, the weighted sum method was provided utilizing a backtracking search optimization [20], the moth swarm algorithm [21], etc. In this optimization problem, weights are assigned to the objectives, and the weighted sum of the objectives is minimized. The OPF problem is solved using linear scalarization or weighted-sum-based multi-objective optimization [22-25], in which every objective is given a weight and the summation of weights must be one. In [26], the authors proposed a weighted sum-based differential evolution (DE) algorithm for the MOOPF problem. In the weighted sum-based method, multiple objectives are transformed into a single objective problem by multiplying each objective by weight such that the sum of all weights is one. The authors considered

different objective functions in both normal and contingency conditions. Roy and Paul [27], proposed a krill herd algorithm (KHA) for solving MOOPF problems using the weighted sum-based method. The crossover and mutation operator of the DE algorithm was merged with KHA to enhance the reliability of the solution and also to select a high-quality solution. Ozan [28], proposed an improved Archimedes optimization method for multi/single-objective OPF problems. Many authors used [29, 30] weighted sum-based MOOPF problems with different objectives. The weighted sum-based methods are simple in combining multi-objectives into a single objective with suitable weights. A weighted sum-based method is the basic type of a decomposition-based MOEA method. However, the fundamental disadvantage of this method is that it must be executed multiple times to produce the approximation set. Moreover, the weighted sum-based method fails to obtain the compromised solutions, and in concave optimization problems, the weighted sum-based method produces optimal solutions for one of the objective functions. This approach heavily depends on weights that are assigned to each objective value, and these, in turn, affect the optimal solution. A series of solutions using multi-objective approaches is preferable to a single solution employing a weighted sum strategy for various reasons.

Abido *et. al.* [31] introduced SPEA to address the active and reactive power dispatch problem. SPEA's main drawback is that the beginning population has only one set of non-dominated solutions and the external population is filled with the same ones. This will lead to Pareto optimal front being suboptimal, leading to a non-uniformly distributed Pareto front. Jeyadevi *et. al.* [32], Pareto dominance-based method was adduced as modified NSGA-II to solve the multi-objective optimization of the reactive power dispatch problem, and the controlled elitism method was deployed to preserve the diversity in Pareto-front; to obtain high uniformity, dynamic crowding distance (DCD) based strategy was proposed. Several authors [33-39] proposed Pareto dominance-based multi-objective optimization for OPF. However, Pareto-based methods suffer from limitations. The selection pressure reduces with an increase in the number of objectives and as a result, the effectiveness of the solution deteriorates proportionately to such an extent that a loss of diversity occurs in the population.

While the aforementioned articles focused exclusively on thermal units, a system that combines thermal and wind powers was explored in the literature to achieve the lowest possible generation cost. To specify the boundaries of reactive power generation ability, Panda *et. al.* [40] suggested a modified bacteria foraging algorithm (MBFA) and built the DFIG model within the OPF architecture. Static synchronous compensation an external reactive power assisting was utilized in [41] to examine a network having wind and thermal sources, and the

OPF issue was handled using the ant colony algorithm and MBFA. In an OPF dispatching program, a stochastic model of wind generation was described in [42]. Included in [43] was the DFIG wind turbine model. [44] presents the OPF model for a hybrid model with PV, a diesel generator, and a battery that operates in isolated mode. In [45], pumped hydro was presented as an alternative method of storage for an autonomous hybrid system composed of PV, wind, and diesel generation. In conclusion, the OPF including thermal, wind, PV, and PEV powers requires additional investigation.

In the literature, numerous single-objective problems of OPF have been resolved. In the current socio-economic environment, it becomes vital to evaluate multiple objectives for OPF. In the past, the typical formulation of OPF consisted of a single target, which was primarily the minimization of generation cost. In several countries, legislation and the installation of a carbon tax have heightened the significance of decreasing greenhouse gas emission. Maintaining power quality necessitates low voltage fluctuations from the desired voltage, and any improvement in power loss provides utilities a financial advantage. Therefore, the MOOPF problem must take into account emission, voltage variation, and power loss in addition to the cost. Since this MOOPF problem is highly non-linear and aims are frequently contradictory, it necessitates the application of effective techniques. An appropriate MOEA can yield a Pareto front (PF) with multiple non-dominated optimal values for balancing multiple objectives.

Several researchers expanded their work on OPF utilizing hybrid heuristic-based multi-objective optimization algorithms[46, 47]. Nonetheless, as the number of objective functions increases, so does the size of the objective space. Therefore, nearly all solutions became non-dominant with each other. This worsens the selection pressure on the PF, a collection of all Pareto-optimal solutions, and leads to a population diversity loss during the evolution as well as a slower pace of convergence for MOPs [48, 49].

The MOEAs are normally modeled to tackle different conflicting objectives, such as maximizing the spread of solutions along the Pareto front (i.e., diversity) and minimizing the distance between the solutions along the Pareto front (i.e., convergence) [50, 51]. The trade-off between convergence and diversity is important to choose a good quality solution among the solutions obtained. Therefore, to attain a balance between exploration and exploitation, several hybrid MOEAs are proposed in this thesis for solving the OPF problem.

## **2.2 Motivation**

In addition to the benefits cited in the existing literature for various optimization strategies, there are also certain drawbacks. The limitations are as follows:

- In the literature, the OPF problem is typically written as a single objective optimization problem [9–17], however, the practical OPF problem has several objectives, and trade-off solutions play a crucial part in power system decision-making.
- The weighted-sum-based technique [20-30] is easy to construct and apply to multi-objective problems. This strategy turns a MOP into a single-objective problem by combining weighted objectives. Apart from the merits, the demerits are: (i) It is incapable of dealing with non-convex Pareto fronts (PF) or the method yields solutions that are optimal in one of the objective functions for non-concave PF and (ii) The weights assigned to the objectives have a substantial effect on the optimal solutions.
- The Pareto-oriented MOEAs [31-39] are gaining importance because they outperform the constraints of weighted-sum-based MOEAs. The solutions are prioritized according to Pareto rather than weighted objectives, which enhances MOEA convergence. Then, the crowding distance method is applied to ensure the diversity of the solutions in the PF. In addition to their benefits, Pareto-based MOEAs have the following disadvantages: (i) In dominance-based approaches, it may be impossible to ensure a level of convergence, and it is difficult to obtain a particularly regular spacing of solutions along the PF. (ii) As objective space expands, nearly all solutions inside a population become non-dominant with one another [48]. (iii) Because dominance resistance solutions exist [49], selection pressure degrades and it may lead to the loss of population diversity during the evolutionary process, and it degrades the effectiveness of MOEA [50], and (iv) Pareto dominance may not give any assurance that the solution provided is an optimal one, as there is no indicator of performance during the evolution.
- In a power system, integrating RESs like WECS and SPVS with conventional OPF is necessary to consider the impact of uncertainty of these sources. The uncertain nature of WECS and SPVS are modeled using PDFs and their uncertainty cost is calculated using Monte-Carlo simulations.
- In addition to RESs, integrating the PEVs with conventional OPF to consider the impact of uncertainty of these sources becomes necessary. The uncertain nature of PEVs is modeled using PDFs and their uncertainty cost is calculated using Monte-Carlo simulations.
- The OPF problem is a constrained optimization problem, which requires an efficient CHM in combination with an evolutionary algorithm to obtain feasible optimal solutions. The commonly used one is the static penalty approach here a penalty is applied to the fitness of an infeasible individual for breaching limitations.

- However, the drawback with the static penalty-based method is that the accuracy of OPF suffers due to the huge error associated with penalty factors. The penalty factors of each objective that are needed to be added to the objective function are fine-tuned by trial and error.

### 2.3 Objectives of the Research

The objective of the research work is to design a multi-objective framework to handle issues with OPF problems in power systems.

The research contributions are as follows:

- A new hybrid decomposition and local-dominance based MOEA was proposed for the OPF problem. Combining decomposition and dominance approaches produced qualitatively and quantitatively distinct compromised solutions along the Pareto optimal front. In this approach, the static penalty-based CHM is proposed to handle equality and inequality restrictions of the OPF problem. In addition, a fuzzy technique is applied to Pareto-optimal solutions to determine the optimal trade-off solution.
- A new hybrid decomposition and summation of normalized objectives with an improved diversified selection-based MOEA including WECS and SPVS uncertainty were proposed for the OPF problem. This chapter suggests a novel CHM that adds the penalty adaptively and avoids parameter dependence on penalty calculation. The summation-based sorting and enhanced diverse selection were applied to increase the diversity of MOEA. On OPF cost analysis, the impact of RES like WECS and SPVS on integration is evaluated. To reduce the total generation cost, the OPF problem takes into account the cost of RESs to study the influence of intermittent and unpredictable renewable sources on operation cost. Weibull and Lognormal PDFs were used, respectively, to describe the uncertainty of WECS and SPVS sources.
- A new hybrid decomposition and summation of normalized objectives with improved diversified selection-based MOEA including WECS, SPVS, and PEVs uncertainty were proposed for the OPF problem. The MOOPF problem was solved using a unique CHM that adaptively adds the penalty and avoids the parameter relying on the penalty calculation. The summation-based sorting and enhanced diverse selection were applied to increase the diversity of MOEA. In addition, a fuzzy technique is applied to Pareto-optimal solutions to determine the optimal trade-off solution. The impact of intermittence of WECS, SPVS, and PEVs integration was considered for optimal cost analysis. The uncertainty associated with WECS, SPVS, and PEV systems was

represented using PDFs and its uncertainty cost was calculated using Monte-Carlo simulations (MCSs).

- A novel hybrid decomposition and invasive weed optimization (IWO) based MOEA was proposed for the OPF problem. The standard OPF problem was transformed into a stochastic OPF by incorporating the uncertainty of WECS, SPVS, and PEV systems. The MOOPF problem was solved using a unique CHM that adaptively inserts the penalty and avoids the parameter relying on penalty calculation. The IWO technique's selection qualities were utilized to boost the diversity of the proposed method. Monte Carlo simulations were used to assess the generation cost of WECS, SPVS, and PEVS in an effort to lower the total generation cost. Weibull, Lognormal, and Normal PDFs were used to characterize the unpredictability of WECS, SPVS, and PEV sources, respectively.

## 2.4 Thesis Organization

The thesis is organized as follows:

**Chapter 1** introduces the OPF problem and its importance in monitoring and operation of the network. It describes briefly the necessities of the OPF problem and the impact of WECS, SPVS, and PEVS penetrations on the power system.

**Chapter 2** presents a comprehensive literature overview of the OPF issue in a power system and discusses the existing methods and their strengths and weaknesses. It provides details of methods used to formulate the optimal power flow problem such as single objective and multi-objective frameworks and discusses different optimization techniques to handle the problem.

Following an extensive literature review on the topic, the motivation for the proposed research work is presented, followed by the objectives of the research, contributions, and organization of the thesis.

**Chapter 3** proposes a new hybrid decomposition and local-dominance based MOEA for the OPF problem. The four objectives considered are minimizing the total generation cost, emission, active power loss, and voltage magnitude deviation. As the OPF problem is a constrained optimization problem, the static penalty-based constrained handling method was used to handle several equal and inequality constraints, which aims to obtain the feasible global optimal solution. The outcomes of the proposed algorithm were compared with NSGA-II and MOPSO methods and demonstrated on IEEE 57-bus and IEEE 118-bus systems.

**Chapter 4** proposes a new hybrid decomposition and summation of normalized objectives with improved diverse selection-based MOEA, including WECS and SPVS generation uncertainty for the OPF problem. This work recommends a novel CHM, that adaptively inserts the penalty and avoids the parameter relying on penalty calculation. The summation-based sorting and enhanced diverse selection were applied to increase the diversity of MOEA. The MOOPF problem was modeled with four objectives: minimizing total generation cost, including WECS and SPVS generation cost, emission, active power loss, and voltage magnitude deviation. In the OPF cost analysis, the influence of RESs such as WECS and SPVS on integration was examined. To minimize the overall cost, the cost of RESs was factored into the OPF to study the influence of intermittent and unpredictable renewable sources on cost and operation. The uncertainty of WECS and SPVS was described using Weibull and Lognormal PDFs respectively. The versatility of the proposed method was demonstrated on IEEE 57-bus and IEEE 118-bus systems and the results obtained were compared with NSGA-II, and MOPSO algorithms to demonstrate the superiority of the proposed method.

**Chapter 5** proposes a new hybrid decomposition and summation of normalized objectives with improved diversified selection-based MOEA including WECS, SPVS, and PEVs uncertainty for the OPF problem. The MOOPF problem includes minimization of the total generation cost, emission, active power loss, and voltage magnitude deviation as objectives, and a novel CHM, that adaptively inserts the penalty and avoids the parameter relying on penalty calculation. The summation-based sorting and enhanced diverse selection were applied to increase the diversity of MOEA. In addition, a fuzzy technique is applied to Pareto-optimal solutions to determine the optimal trade-off solution. The impact of intermittence of WECS, SPVS, and PEVs integration was considered for optimal cost analysis. The uncertainty associated with WECS, SPVS, and PEV systems was represented using PDFs and the uncertainty cost was calculated using Monte-Carlo simulation. The superiority of the proposed method was validated by comparing it with NSGA-II, and MOPSO algorithms and tested on IEEE 57-bus and IEEE 118-bus systems.

**Chapter 6** proposes a new hybrid decomposition and invasive weed optimization (IWO) based MOEA for the OPF problem. The standard OPF problem was transformed into a stochastic OPF by incorporating the uncertainty of WECS, SPVS, and PEV systems. This chapter presents a new CHM that adaptively inserts the penalty and avoids the parameter relying on penalty calculation. The IWO technique's selection qualities were utilized to increase the diversity of MOEA. The MOOPF problem includes minimization of the total generation cost,

emission, active power loss, and voltage magnitude deviation as objectives. The generation cost of WECS, SPVS, and PEV sources was examined using Monte Carlo simulations to reduce the total generation cost. Weibull, Lognormal, and Normal PDFs were used to characterize the unpredictability of WECS, SPVS, and PEV sources, respectively. The impact of WECS, SPVS, and PEV uncertainties, was taken into account to validate the proposed method. The superiority of the proposed method was validated by comparing it with NSGA-II, and MOPSO algorithms and tested using IEEE 57-bus and IEEE 118-bus systems.

**Chapter 7** summarizes the research contribution, findings, and observations on the proposed research work. Then it presents the scope for future work on the topic.

## **2.5 Summary**

This chapter provides a summary of existing literature on OPF in power systems. With the penetration of renewable energy sources, power system operation becomes more challenging. This chapter discusses different OPF solutions in literature, constraint handling methods, and literature on the integration of uncertain sources like WECS, SPVS, and PEVs. This chapter also deals with MOOPF problem-related research and presents a discussion of various types of multi-objective evolutionary algorithms. Furthermore, motivation, contributions of the study, and organization of the thesis are presented in this chapter.

## Chapter 3

### A Novel Hybrid Multi-Objective Evolutionary Algorithm Based on Decomposition and Local Dominance for the Optimal Power Flow

#### 3.1 Introduction

In this chapter, a novel hybrid decomposition and local dominance-based MOEA was proposed for the OPF problem with four conflicting objectives including minimization of total generation cost, emission, active power loss, and voltage magnitude deviation. A penalty method was used to address multiple MOOPF problem restrictions. In addition, a fuzzy technique was employed to identify the best compromise solution among Pareto-optimal solutions. The decomposition and local dominance methods were employed to get a uniformly distributed Pareto front and improved convergence characteristics. The suggested method combines decomposition and local dominance strategies to enhance effectiveness, (i.e., the exploring and exploitation) of MOEA. To evaluate the suggested method IEEE 57-bus, and IEEE 118-bus systems were studied, and the obtained results were evaluated using the NSGA-II and MOPSO algorithms. The contributions of this chapter are as follows:

- i. Proposed a new hybrid decomposition and local dominance-based MOEA for the OPF problem.
- ii. The trade-off between convergence and diversity in the solutions was obtained using hybrid decomposition and dominance methods.
- iii. Using a fuzzy technique, the optimal trade-off solution among Pareto-optimal solutions was determined.
- iv. An efficient CHM to tackle constraints in the MOOPF problem was used.

#### 3.2 Problem Formulation

The MOOPF seeks to optimize objective functions while adhering to limitations by identifying the optimal decision variables. Accordingly, the MOOPF problem is stated as follows:

$$\text{Min } F(x, u) = [F_1(x, u), F_2(x, u), \dots, F_m(x, u)] \quad (3.1)$$

Subject to:

$$g(x, u) = 0 \quad (3.2)$$

$$h(x, u) \leq 0 \quad (3.3)$$

where  $F_m(x, u)$  denotes  $m^{th}$  objective;  $g(x, u)$  and  $h(x, u)$  indicates equality and inequality constraints respectively.

### 3.2.1 Objectives

The MOOPF problem considered the minimization of four objectives: a) total generation cost ( $J_1$ ), b) emission ( $J_2$ ), c) active power loss ( $J_3$ ), and d) voltage magnitude deviation ( $J_4$ ).

*a) Total generation cost (\$/h):*

The quadratic connection approximates the relationship between the cost of generation and power output. The following expression describes the total generation cost from thermal generators:

$$\text{Min } J_1 = \sum_{i=1}^{N_G} (a_i + b_i P_{Gi} + c_i P_{Gi}^2) \quad (3.4)$$

where  $N_G$  is the number of generators;  $P_{Gi}$  is the  $i^{th}$  generator output active power;  $a_i, b_i, c_i$  is the  $i^{th}$  generator cost coefficients;

*b) Emission (ton/h):*

The generation of electric power from traditional fossil fuels would result in the emission of hazardous gases into the atmosphere. The following expression describes the total emission from thermal generators:

$$\text{Min } J_2 = \sum_{i=1}^{N_G} (\alpha_i + \beta_i P_{Gi} + \gamma_i P_{Gi}^2 + \delta_i e^{\varepsilon_i P_{Gi}}) \quad (3.5)$$

where  $\alpha_i, \beta_i, \gamma_i, \delta_i, \varepsilon_i$  are the  $i^{th}$  generator emission coefficients;

*c) Active power loss (MW):*

The following equation can be used to express active power loss:

$$\text{Min } J_3 = \sum_{k=1}^{N_L} \left( G_k (V_i^2 + V_j^2 - 2V_i V_j \cos \theta_{ij}) \right) \quad (3.6)$$

where  $N_L$  is the number of lines;  $\theta_{ij}$  is the voltage angles between buses  $i$  and  $j$ ;  $G_k$  indicates conductance of the  $k^{th}$  branch;  $V_i, V_j$  is the voltage magnitudes at  $i^{th}$  and  $j^{th}$  bus respectively.

*d) Voltage magnitude deviation (p.u.):*

The voltage variation is the sum of all voltage variations at load buses in the network relative to the reference voltage. The mathematical expression is as follows:

$$\text{Min } J_4 = \sum_{i=1}^{N_{PQ}} |(V_i - V_{ref})| \quad (3.7)$$

where  $N_{PQ}$  is the number of PQ buses;  $V_{ref}$  is the reference voltage set to 1 p.u.;  $V_i$  is the  $i^{th}$  load bus voltage.

### 3.2.2 Constraints

The MOOPF objectives are subjected to the following equality and inequality constraints.

*a) Equality constraints:*

The equality constraints are power-balancing equations in which the sum of the generations of the real and reactive powers is equal to their corresponding demands and losses.

- Power flow constraints

$$P_{Gi} - P_{Di} - V_i \sum_{j=1}^{N_B} V_j (G_{ij} \cos \theta_{ij} + B_{ij} \sin \theta_{ij}) = 0; i = 1, 2, \dots, N_B \quad (3.8)$$

$$Q_{Gi} - Q_{Di} - V_i \sum_{j=1}^{N_B} V_j (G_{ij} \sin \theta_{ij} - B_{ij} \cos \theta_{ij}) = 0; i = 1, 2, \dots, N_B \quad (3.9)$$

where  $N_B$  is the number of buses;  $P_{Gi}$ ,  $Q_{Gi}$ , and  $P_{Di}$ ,  $Q_{Di}$  represent the real, reactive power generations and demands at the  $i^{th}$  bus, respectively;  $G_{ij}$ ,  $B_{ij}$  is the conductance, susceptance of lines between buses  $i$  and  $j$  respectively;

*b) Inequality constraints:*

The operational limitations on generators, transformers, and shunt devices, as well as the security requirements on lines and load buses, constitute inequality constraints.

- Generator constraints: The boundary limits of real and reactive powers and voltage magnitude of the generator buses are expressed as follows:

$$P_{Gi}^{min} \leq P_{Gi} \leq P_{Gi}^{max}; i = 1, 2, \dots, N_G \quad (3.10)$$

$$Q_{Gi}^{min} \leq Q_{Gi} \leq Q_{Gi}^{max}; i = 1, 2, \dots, N_G \quad (3.11)$$

$$V_{Gi}^{min} \leq V_{Gi} \leq V_{Gi}^{max}; i = 1, 2, \dots, N_G \quad (3.12)$$

- Shunt VAR compensator constraints: The following are the boundary values for shunt compensators:

$$Q_{Ci}^{min} \leq Q_{Ci} \leq Q_{Ci}^{max}; i = 1, 2, \dots, N_C \quad (3.13)$$

- Transformer constraints: The ideal operating limits for tap settings on a transformer are given as follows:

$$T_i^{min} \leq T_i \leq T_i^{max}; i = 1, 2, \dots, N_T \quad (3.14)$$

- Security constraints: The voltage limits of the load buses and the apparent power value of each transmission line, which can be restricted by its maximum capacity, are given as follows:

$$V_{Li}^{min} \leq V_{Li} \leq V_{Li}^{max}; i = 1, 2, \dots, N_{PQ} \quad (3.15)$$

$$|S_{li}| \leq S_{li}^{max}; i = 1, 2, \dots, N_L \quad (3.16)$$

where  $N_C$ ,  $N_T$  is the number of shunt compensators and transformers respectively;  $S_{li}$  and  $S_{li}^{max}$  are the apparent power flow and its max. limit of  $i^{th}$  line;  $P_{Gi}^{min}, P_{Gi}^{max}$  are the limits on real power generation;  $Q_{Gi}^{min}, Q_{Gi}^{max}$  are the limits on reactive power generation;  $V_{Gi}^{min}, V_{Gi}^{max}$  are the limits on generator bus voltages;  $T_i^{min}, T_i^{max}$  are the limits on transformer taps;  $Q_{Ci}^{min}, Q_{Ci}^{max}$  are the limits on shunt compensator;  $V_{Li}^{min}, V_{Li}^{max}$  are the limits on load bus voltages;

### 3.3 Constraint Handling Method

To address the MOOPF problem restrictions, a constraint-handling process was deployed. Boundary limits of the decision variables are self-constrained and can be reset using Eq. (3.18) during simulation. In addition, changes to the equality restrictions of real and reactive power flows can be done during load flow calculation using Newton-Raphson (Polar) method. The remaining constraints (inequality) are handled using the penalty factor approach. In the penalty factor approach, the violated restrictions are multiplied by the punishment factor and added to the corresponding objective value. This can be formulated as shown in Eq. (3.17).

It should be mentioned that the decision variables are self-constrained. The inequality constraints of  $P_{G1}, V_L, Q_G$ , and  $S_l$  can be included in the objective function as quadratic penalty terms. Thus, the augmented objective function will be as:

$$J_{MOOPF}(x, u) = \begin{bmatrix} J_{OPF1}(x, u) \\ \vdots \\ J_{OPFM}(x, u) \end{bmatrix} = \begin{bmatrix} F_{OPF1} + \lambda_P (P_{G1} - P_{G1}^{lim})^2 + \lambda_V \sum_{i=1}^{N_{PQ}} (V_{Li} - V_{Li}^{lim})^2 \\ + \lambda_Q \sum_{i=1}^{N_G} (Q_{Gi} - Q_{Gi}^{lim})^2 + \lambda_S \sum_{i=1}^{N_L} (S_{li} - S_{li}^{lim})^2 \\ \vdots \\ F_{OPFM} + \lambda_P (P_{G1} - P_{G1}^{lim})^2 + \lambda_V \sum_{i=1}^{N_{PQ}} (V_{Li} - V_{Li}^{lim})^2 \\ + \lambda_Q \sum_{i=1}^{N_G} (Q_{Gi} - Q_{Gi}^{lim})^2 + \lambda_S \sum_{i=1}^{N_L} (S_{li} - S_{li}^{lim})^2 \end{bmatrix} \quad (3.17)$$

where  $\lambda_P, \lambda_V, \lambda_Q$  and  $\lambda_S$  are the penalty factors;  $M$  is the number of objective functions;  $x^{lim}$  is the limit value of the independent variable  $x$  and is given as:

$$x^{lim} = \begin{cases} x_{min}; & \text{if } x < x_{min} \\ x; & \text{if } x_{min} \leq x \leq x_{max} \\ x_{max}; & \text{if } x > x_{max} \end{cases} \quad (3.18)$$

### 3.4 Proposed Method

The proposed MOEA is obtained by combining the Pareto-dominance and decomposition techniques to exploit the advantages in both methods and to maintain the balance between exploration and exploitation. The Pareto-dominance and decomposition techniques were incorporated from the NSGA-II [57] and MOEA/D [53] methods.

In Pareto dominance method, the feasible solutions are selected using non-dominated sorting technique to rank the solutions and crowding distance method is employed to improve

the population diversity. However, with increase in objective size dominance methods may not maintain the diversity of the population. On the other hand, Decomposition methods decompose the MOP into multiple sub-problems using weight vectors. The sub-problems are then simultaneously optimized. The neighborhoods are created based on the distance between weights. In each population evolution, neighborhood information is used to choose which solutions to select. The penalty-based intersection (PBI) is utilized to assign relative fitness values to each solution [53]. The PBI is stated below:

$$PBI(X|w, z^*) = d_1 + \theta d_2$$

where  $d_1 = \frac{\|(z^* - F(X)^T \cdot w)\|}{\|w\|}$  and  $d_2 = \|F(X) - (z^* - d_1 \cdot w)\|$

where  $F(X) = [J_1, J_2, J_3, J_4]$  (3.19)

where  $z^*$  is the ideal point,  $w$  is the weight vector, and  $\theta$  be the penalty value.

Randomly generate a population of size 'N', which is equal to the number of weight vectors. The weight vectors with a uniform distribution are created using SSA [54]. Each member of the population is given a weight vector and is associated with a neighborhood. The mating parents are then selected from the nearby region using the minimum angle requirement and a probability of ' $\delta$ '. The typical value set to selection probability ' $\delta$ ' is 0.8. The angle criteria are used to identify weight vectors' nearest neighbors. The vectors with the least angles are chosen to be the neighbors. Based on the angle, a neighborhood is allotted to each weight vector. For every vector, a set of parents is chosen from the neighbors depending on selection probability. If there are no individuals in the given region, the mating parent is selected from the entire population. The angle between the two vectors is given by the formulae [55] as given below:

$$\tan \varphi = \frac{d_2}{d_1}$$

where  $d_1 = \frac{\|w_i^T \cdot w_j\|}{\|w_j\|}$  and  $d_2 = \left\| w_i - d_1 \frac{w_j}{\|w_j\|} \right\|$

where  $i, j = 1, 2, \dots, N$  and  $i \neq j$  (3.20)

where  $\varphi$  = angle between  $d_1$  and  $d_2$ .

The new offspring population is reproduced via crossover and mutation. The old and new populations are partitioned into 'N' sub-populations. The partition is done by comparing the two individuals. For comparing the individuals, the dominance method and PBI are used Eq. (3.19). To choose competent individuals from 'N' subpopulations, the elitist selection procedure is then employed. This procedure is repeated until the termination criterion has been

satisfied. The maximum number of iterations served as the termination criterion for this approach. Using a fuzzy technique, the optimal solution is determined [56].

The steps in the proposed method are as follows:

**Initialization:** Randomly generate initial population ( $P_t$ ) of size 'N' and weight vectors with a uniform distribution using SSA [54] as follows:

$$N(D, M) = \binom{D + M - 1}{M - 1} \text{ for } D > 0 \quad (3.21)$$

Here  $D$  and  $M$  represent the number of divisions for each objective coordinate and objective function respectively.

Run the load flow to determine the fitness value of the chosen objective function and compute the constraint violations. If any constraint violation occurs, it is penalized using Eq. (3.17), and Eq. (3.18).

Find the neighboring solutions, the vectors with the least angles are chosen to be the neighbors. The angle between two vectors is given by Eq. (3.20).

Find the minimum values for all the objectives to form the current ideal point.

**Reproduction:** Select  $N$  mating pairings based on angle requirements. With the probability of  $\delta$ , a pair of mated parents is chosen for each weight vector. To generate new population ( $Q_t$ ) use crossover and mutation.

**Population-partition:** The old ( $P_t$ ) and new ( $Q_t$ ) populations are partitioned into  $N$  subpopulations. Based on the partition, every sub-population has  $N_i$  individual populations. The partition is done by comparing the two individuals.

For Comparing the individuals, the dominance and PBI methods are used. Firstly the dominance between individuals  $x$  and  $y$  is compared. If solution  $x$  is seen as better compared to  $y$ , return true; otherwise, their respective PBI values are compared. The lower the PBI value the better the solution.

**Elitist selection:** Here, all individuals are partitioned into multiple levels. During elitist selection, the individuals for the next-level  $P_{t+1}$  are chosen. Choose the individual from each population subset till 'N' is not exceeded. Otherwise, a random sample is selected from the partitioned population.

Use the fuzzy approach [59] on the final Pareto front to choose the best-compromised solution.

### 3.5 Results and Discussions

The proposed method was executed on MATLAB R2016a and the simulation was carried out on i3-Processor with 4GB RAM. To validate the efficacy of the proposed method, it was compared to NSGA-II [57] and MOPSO [58] algorithms. The control parameters of the proposed method, NSGA-II, and MOPSO are given in Table 3.1, these values are selected in accordance with the global optimal solution. A total of five cases were considered on IEEE 57-bus, and IEEE 118-bus systems to test the efficiency of the proposed method for the MOOPF problem. The various cases considered are given in Table 3.2. The description of the test systems was given in Table 3.3. Appendices A and B contain system data for the IEEE 57-bus, and 118-bus, respectively.

**Table 3.1:** Control parameters of the proposed method, NSGA-II, and MOPSO.

S. No.	Method	Control parameters
1.	<b>Proposed method</b>	<b>Population size (<math>N</math>) = 100, number of divisions made along the every objective (<math>D</math>) = 12, neighborhood size (<math>T</math>) = 20, crossover probability (<math>Pc</math>) = 1.0, mutation probability (<math>Pm</math>) = 0.05, and maximum iterations= 100.</b>
2.	NSGA-II [57]	$N = 100, P_c = 0.8, P_m = 0.01$ , and max. iterations = 100.
3.	MOPSO [58]	$N = 100, C_1 = C_2 = 2, W = 0.5$ , and max. iterations = 100.

### 3.5.1 IEEE 57-bus system

The proposed method was tested on an IEEE 57-bus system [59], which has 7 thermal generators (#1 bus as a slack bus), 80 lines, 17 off-nominal transformers, 3 shunt VAR compensators, the real and reactive power demand of 1250.80 MW and 336.40 MVAR, respectively.

#### a) *Case-1: Minimize $J_1$ , and $J_2$ simultaneously*

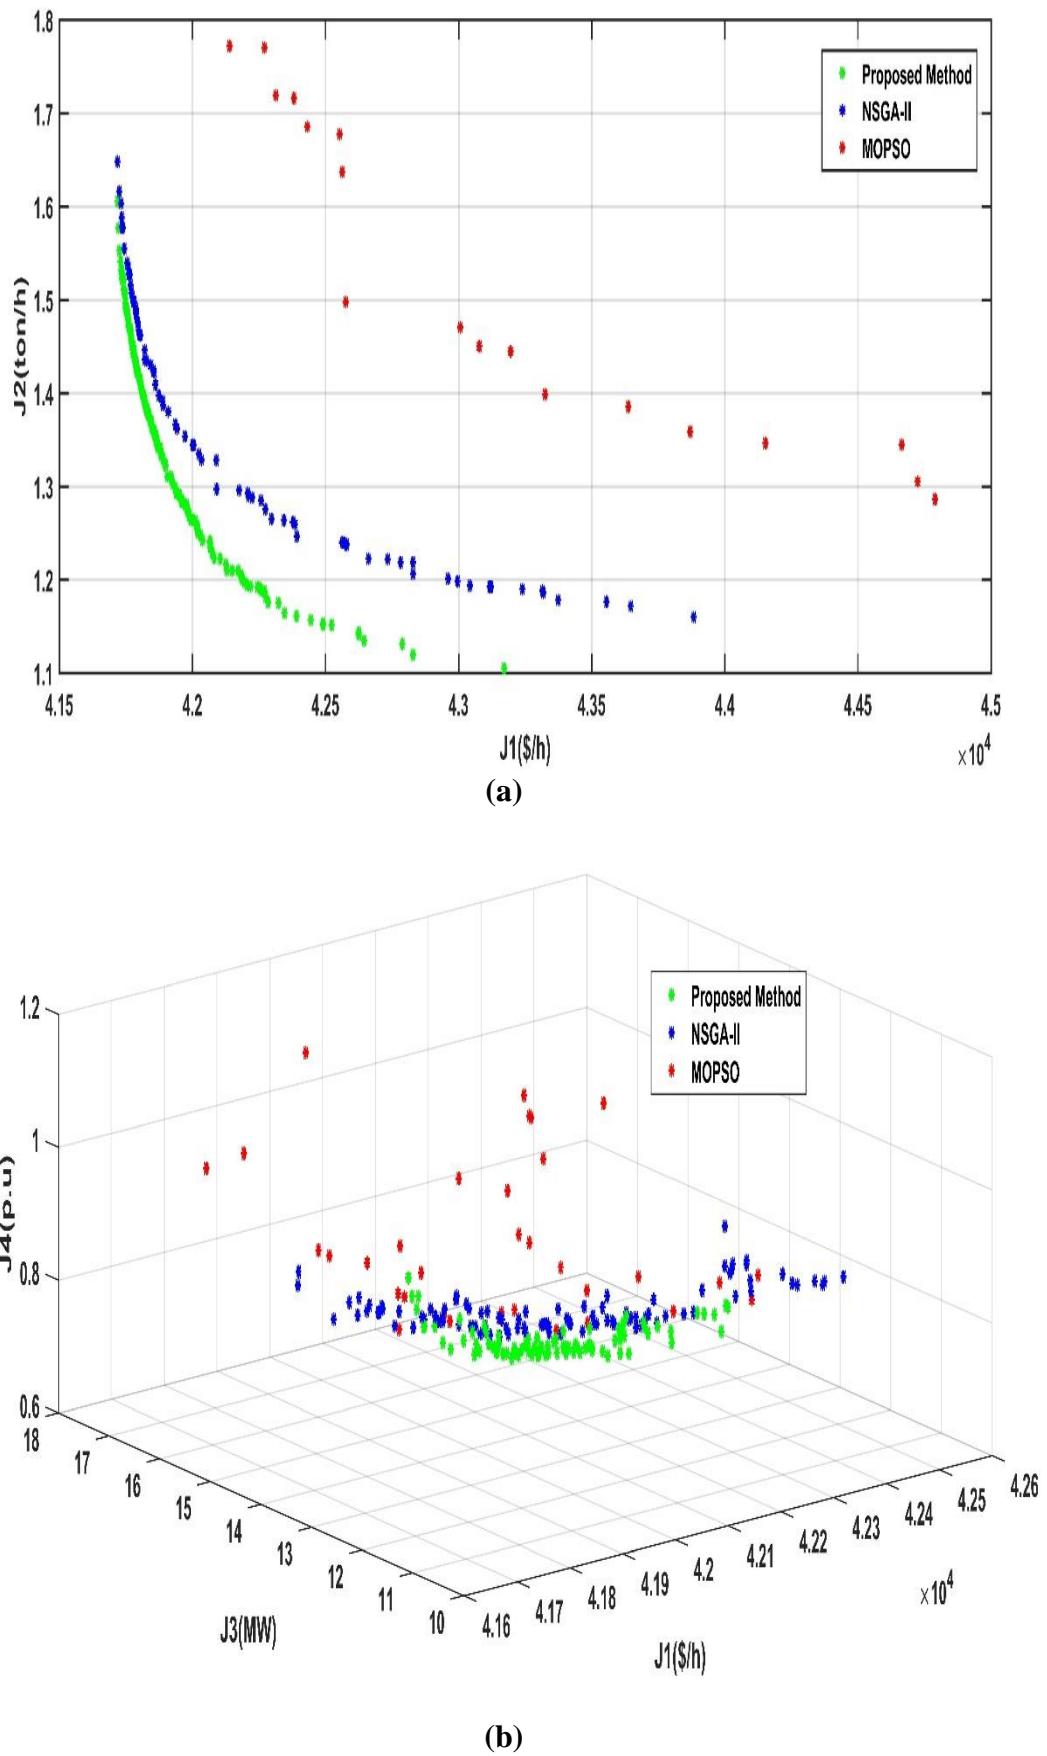

In this case, the proposed method was simulated by considering two objectives  $J_1$  and  $J_2$ . The Pareto-optimal fronts (PFs) observed in this case, are depicted in Figure 3.1. The optimal decision variables obtained by the proposed method are presented in Table 3.4. The proposed method obtains a total generation cost of **42082.05\$/h** and emission of **1.2233ton/h**. NSGA-II [57] gives 42091.76\$/h, 1.2971ton/h and MOPSO [58] gives 42576.62\$/h, 1.4976ton/h respectively as shown in Table 3.5.

#### b) *Case-2: Minimize $J_1$ , $J_3$ , and $J_4$ simultaneously*

In this case, the proposed method was simulated by considering three objectives  $J_1$ ,  $J_3$ , and  $J_4$ . The Pareto-optimal fronts (PFs) observed in this case are depicted in Figure 3.1. The optimal decision variables obtained by the proposed method are presented in Table 3.4. The proposed method obtains a total generation cost of **41919.00\$/h**, active power loss of **12.2322MW**, and voltage magnitude deviation of **0.8198p.u**. NSGA-II [57] gives 42001.15\$/h, 12.2673MW, 0.8312p.u and MOPSO [58] gives 42770.65\$/h, 16.7486MW, 1.2838p.u respectively as shown in Table 3.5.

#### c) *Case-3: Minimize $J_1$ , $J_2$ , $J_3$ , and $J_4$ simultaneously*

In this case, the proposed method was simulated by considering four objectives  $J_1$ ,  $J_2$ ,  $J_3$ , and  $J_4$ . The optimal decision variables obtained by the proposed method are presented in Table 3.4. The proposed method obtains a total generation cost of **42419.00\$/h**, emission of **1.3065ton/h**, active power loss of **12.3121MW**, and voltage magnitude deviation of **0.8918p.u**. NSGA-II [57] gives 42601.15\$/h, 1.4190ton/h, 12.3673MW, 1.0315p.u and MOPSO [58] gives 42970.14 \$/h, 1.4998ton/h, 15.7126MW, 1.3638p.u respectively as shown in Table 3.5.

### 3.5.2 IEEE 118-bus system

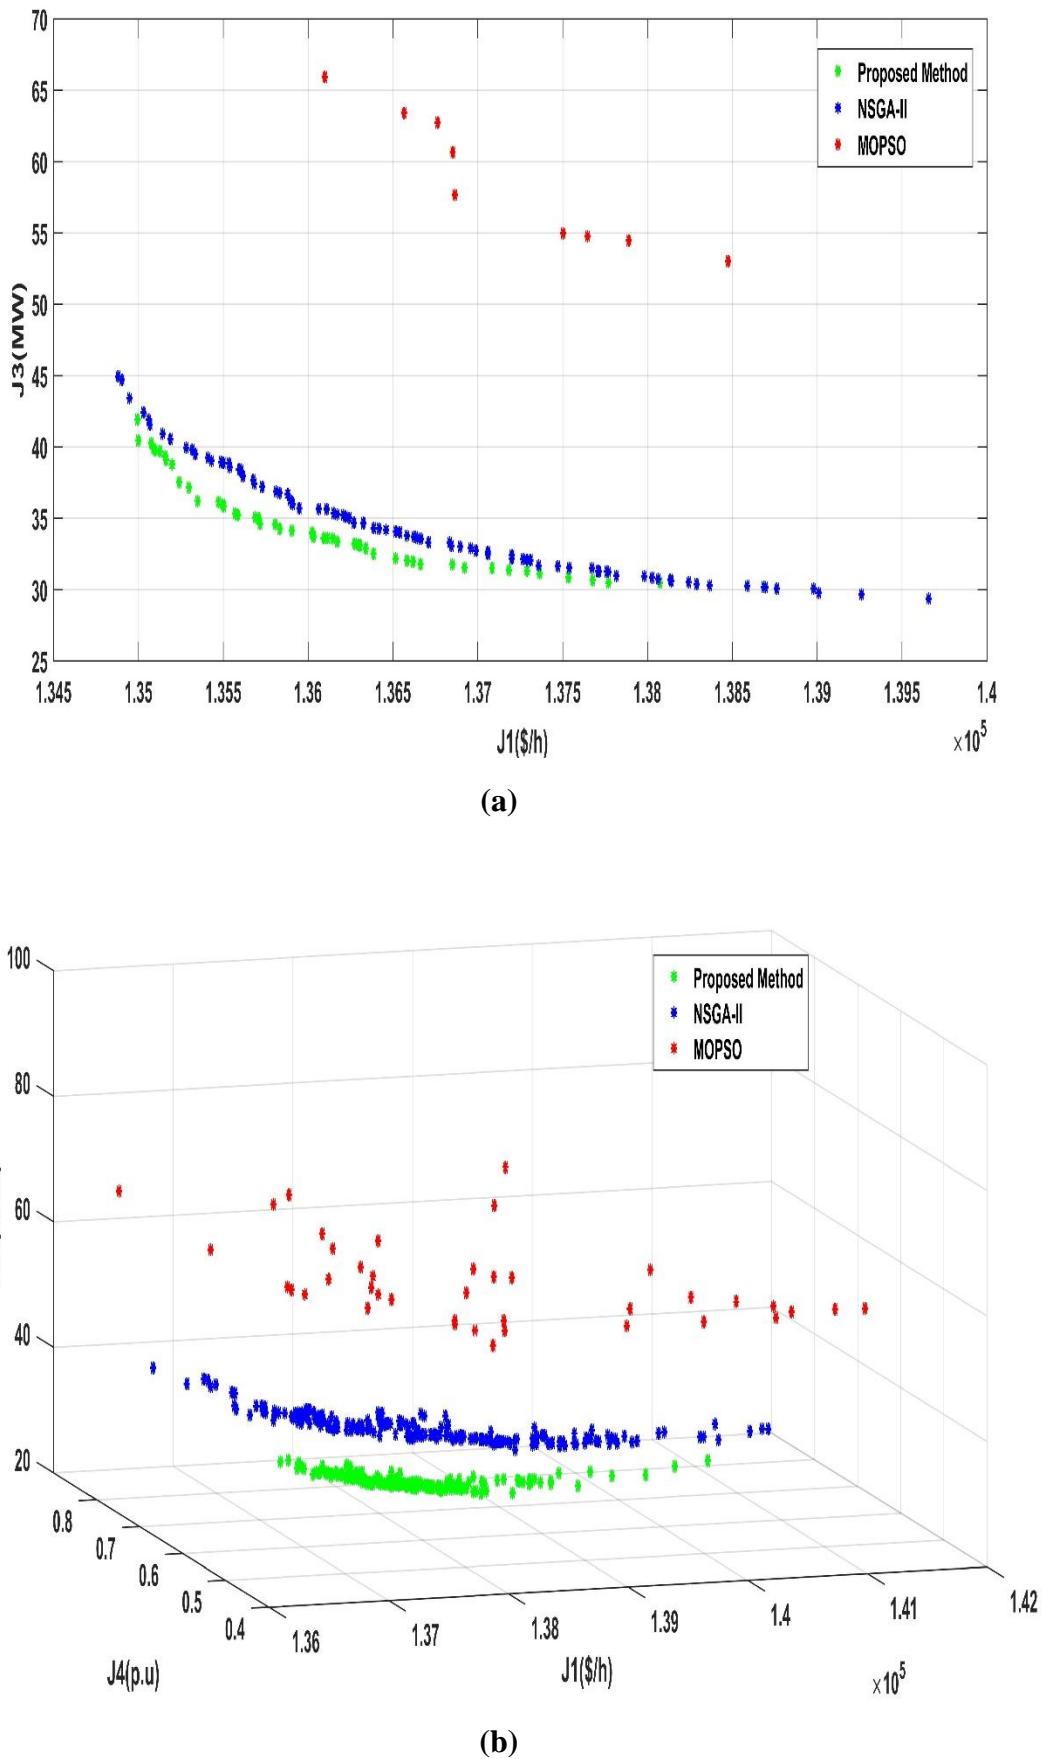

The proposed technique has also been investigated for the IEEE 118-bus system [59], which has 54 thermal generator buses (# 69 bus as a slack bus), 186 lines, 9 off-nominal transformers, 12 shunt VAR compensators, the real and reactive power demand of 4242.00MW and 1439.00MVAR, respectively.

#### *a) Case-4: Minimize $J_1$ and $J_3$ simultaneously*

In this case, the proposed method was simulated by considering two objectives  $J_1$  and  $J_3$ . The Pareto-optimal fronts (PFs) observed in this case are shown in Figure 3.2. The optimal decision variables obtained by the proposed method are presented in Table 3.6. The proposed method obtains a total generation cost of **135716.72\$/h**, and active power loss of **34.5983MW**. NSGA-II [57] gives 135948.25\$/h, 35.6852MW and MOPSO [58] gives 136865.18\$/h, 57.6587MW respectively as shown in Table 3.7.

#### *b) Case-5: Minimize $J_1$ , $J_3$ , and $J_4$ simultaneously*

In this case, the proposed method was simulated by considering three objectives  $J_1$ ,  $J_3$ , and  $J_4$ . The Pareto-optimal fronts (PFs) observed in this case are shown in Figure 3.2. The optimal decision variables obtained by the proposed method are presented in Table 3.6. The proposed method obtains a total generation cost of **137715.17\$/h**, active power loss of **33.3462MW**, and voltage magnitude deviation of **0.4779p.u.** NSGA-II [57] gives 138441.48\$/h, 37.8479MW, 0.5067p.u and MOPSO [58] gives 138501.58\$/h, 51.5057MW, 0.5750p.u respectively as shown in Table 3.7.

**Fig. 3.2:** IEEE 118-bus system: Pareto-optimal fronts. a) Case-4, and b) Case-5.

### 3.6 Summary

In this work, a new hybrid decomposition and local dominance-based MOEA was proposed for solving the OPF problem. Minimizing the total generation cost, emission, active power loss, and voltage magnitude deviation are the four objectives that were considered. The hybridization of decomposition and dominance approaches increases the convergence and diversity of Pareto optimum front solutions. The static penalty-based method was deployed to tackle both equality and inequality constraints. In addition, a fuzzy technique was used to obtain the best-compromised solutions from the Pareto-optimal set. The proposed method was tested on IEEE 57-bus and IEEE 118-bus systems using different cases to validate its efficiency and the obtained results were compared with NSGA-II and MOPSO methods. This work is restricted to conventional MOOPF with only thermal units, to assess the impact of wind, and solar integration on the MOOPF problem next work is proposed.

## Chapter 4

# A New Hybrid Decomposition and Summation of Normalized Objectives with Improved Diversified Selection Based Multi-Objective Evolutionary Algorithm Including Wind, and Solar Uncertainty for the Optimal Power Flow

### 4.1 Introduction

This chapter proposes a new hybrid decomposition, and summation of normalized objectives with improved diversified selection-based MOEA for the OPF including WECS and SPVS uncertainty. This work recommends a novel CHM, that adaptively inserts penalty and avoids the parameter relying on penalty calculation. The summation-based sorting and enhanced diverse selection techniques are employed to increase the diversity of MOEA. The MOOPF is defined using four objectives: minimizing total generating cost, comprising WECS and SPVS generation cost, emission, active power loss, and voltage magnitude deviation. In the OPF cost study, the influence of RES such as WECS and SPVS on integration is taken into account. To reduce the total generation cost, the cost of RESs is factored into the OPF issue to study the impact of intermittent and unpredictable renewable sources on cost and operational viability. The uncertainty of WECS and SPVS sources was described using Weibull and Lognormal PDFs respectively. The efficacy of the proposed method was tested on IEEE 57-bus, and 118-bus systems under all possible RES situations using Monte Carlo simulations. The work makes the following contributions:

- i. Proposing a novel MOEA based on decomposition and summation of normalized objectives with improved diversified selection for the MOOPF problem.
- ii. Integrating RESs like WECS and SPVS with conventional OPF to consider the impact of the uncertain nature of these sources.
- iii. Modeling the uncertain nature of WECS and SPVS using PDFs and calculating the uncertain cost using Monte-Carlo simulations.
- iv. Using a new CHM called superiority of feasible solution (SF) to tackle constraints in the MOOPF problem.

### 4.2 Problem Formulation

The MOOPF problem's objective functions and constraints are stated as follows:

### 4.2.1 Objectives

The MOOPF problem was formulated using four objectives: minimizing a) total generation cost including the cost of WECS and SPVS generation ( $J_1$ ), b) emission ( $J_2$ ), c) active power loss ( $J_3$ ), and d) voltage magnitude deviation ( $J_4$ ).

*a) Total generation cost (\$/h):*

The overall generating cost is the sum of the generation cost of thermal, WECS, and SPVS and is expressed by the following equation:

$$\begin{aligned} \text{Min } J_1 = & \sum_{i=1}^{N_{TG}} (a_i + b_i P_{TGi} + c_i P_{TGi}^2) \\ & + \sum_{j=1}^{N_{WG}} [C_{W,j}(P_{ws,j}) + C_{RW,j}(P_{ws,j} - P_{wav,j}) + C_{PW,j}(P_{wav,j} - P_{ws,j})] \\ & + \sum_{k=1}^{N_{SG}} [C_{S,j}(P_{ss,k}) + C_{RS,k}(P_{ss,k} - P_{sav,k}) + C_{PS,k}(P_{sav,k} - P_{ss,k})] \end{aligned} \quad (4.1)$$

where  $N_{TG}$ ,  $N_{WG}$ , and  $N_{SG}$  are the number of thermal, WECS, and SPVS respectively;  $P_{ws,j}$ , and  $P_{ss,k}$  is the scheduled powers of  $j^{th}$  WECS and  $k^{th}$  SPVS respectively;  $P_{wav,j}$ , and  $P_{sav,k}$  are the actual powers of  $j^{th}$  WECS and  $k^{th}$  SPVS respectively;  $P_{TGi}$  is the  $i^{th}$  thermal generator output power;  $a_i$ ,  $b_i$ ,  $c_i$  is the  $i^{th}$  thermal generator cost coefficients;

*b) Emission (ton/h):*

The generation of electric power from traditional fossil fuels would result in the emission of hazardous gases into the atmosphere. The following expression describes the total emission from thermal generators:

$$\text{Min } J_2 = \sum_{i=1}^{N_{TG}} (\alpha_i + \beta_i P_{TGi} + \gamma_i P_{TGi}^2 + \delta_i e^{\varepsilon_i P_{TGi}}) \quad (4.2)$$

where  $\alpha_i$ ,  $\beta_i$ ,  $\gamma_i$ ,  $\delta_i$ ,  $\varepsilon_i$  are the  $i^{th}$  thermal generator emission coefficients;

*c) Active power loss (MW):*

The following equation can be used to express active power loss:

$$\text{Min } J_3 = \sum_{k=1}^{N_L} \left( G_k (V_i^2 + V_j^2 - 2V_i V_j \cos \theta_{ij}) \right) \quad (4.3)$$

where  $N_L$  is the number of lines;  $\theta_{ij}$  represents the voltage angle between buses  $i$  and  $j$ ;  $G_k$  shows the conductance of branch  $k$ ;  $V_i$ ,  $V_j$  is the voltage magnitudes at  $i^{th}$  and  $j^{th}$  buses respectively.

*d) Voltage magnitude deviation (p.u.):*

The voltage variation is the sum of all voltage variances at load buses in the network relative to the reference voltage. The mathematical expression is as follows:

$$\text{Min } J_4 = \sum_{i=1}^{N_{PQ}} |(V_i - V_{ref})| \quad (4.4)$$

where  $N_{PQ}$  is the number of PQ buses;  $V_{ref}$  is the reference voltage set to 1 p.u.;  $V_i$  is the  $i^{th}$  load bus voltage.

#### 4.2.2 Constraints

The MOOPF objectives are subjected to the following equality and inequality constraints.

a) Equality constraints:

The equality constraints are power-balancing equations in which the sum of the generations of the real and reactive powers is equal to their corresponding demands and losses.

- Power flow constraints

The overall demand and losses throughout the system are equal to the total real and reactive power delivered:

$$P_{Gi} - P_{Di} - V_i \sum_{j=1}^{N_B} V_j (G_{ij} \cos \theta_{ij} + B_{ij} \sin \theta_{ij}) = 0; i = 1, 2, \dots, N_B \quad (4.5)$$

$$Q_{Gi} - Q_{Di} - V_i \sum_{j=1}^{N_B} V_j (G_{ij} \sin \theta_{ij} - B_{ij} \cos \theta_{ij}) = 0; i = 1, 2, \dots, N_B \quad (4.6)$$

where  $N_B$  is the number of buses;  $P_{Gi}$ ,  $Q_{Gi}$ , and  $P_{Di}$ ,  $Q_{Di}$  are the real, reactive power generations and demands at the  $i^{th}$  bus, respectively;  $G_{ij}$ ,  $B_{ij}$  is the conductance, susceptance of lines between buses  $i$  and  $j$  respectively;

b) Inequality constraints:

The operational limitations on generators, transformers, and shunt devices, as well as the security requirements on lines and load buses, constitute inequality constraints.

- Generator constraints: The boundary limits of real and reactive powers and voltage magnitude of the generator buses are expressed as follows:

$$P_{TGi}^{\min} \leq P_{TGi} \leq P_{TGi}^{\max}; i = 1, 2, \dots, N_{TG} \quad (4.7)$$

$$P_{WGi}^{\min} \leq P_{WGi} \leq P_{WGi}^{\max}; i = 1, 2, \dots, N_{WG} \quad (4.8)$$

$$P_{SGi}^{\min} \leq P_{SGi} \leq P_{SGi}^{\max}; i = 1, 2, \dots, N_{SG} \quad (4.9)$$

$$Q_{TGi}^{\min} \leq Q_{TGi} \leq Q_{TGi}^{\max}; i = 1, 2, \dots, N_{TG} \quad (4.10)$$

$$Q_{WGi}^{\min} \leq Q_{WGi} \leq Q_{WGi}^{\max}; i = 1, 2, \dots, N_{WG} \quad (4.11)$$

$$Q_{SGi}^{\min} \leq Q_{SGi} \leq Q_{SGi}^{\max}; i = 1, 2, \dots, N_{SG} \quad (4.12)$$

$$V_{Gi}^{\min} \leq V_{Gi} \leq V_{Gi}^{\max}; i = 1, 2, \dots, N_G \quad (4.13)$$

- Shunt compensator constraints: The following are the boundary values for shunt compensators:

$$Q_{Ci}^{min} \leq Q_{Ci} \leq Q_{Ci}^{max}; i = 1, 2, \dots, N_C \quad (4.14)$$

- Transformer constraints: The ideal operating limits for tap settings on a transformer are given as follows:

$$T_i^{min} \leq T_i \leq T_i^{max}; i = 1, 2, \dots, N_T \quad (4.15)$$

- Security constraints: The voltage limits of the load buses and the apparent power value of each transmission line, which can be restricted by its maximum capacity, are given as follows:

$$V_{Li}^{min} \leq V_{Li} \leq V_{Li}^{max}; i = 1, 2, \dots, N_{PQ} \quad (4.16)$$

$$|S_{li}| \leq S_{li}^{max}; i = 1, 2, \dots, N_L \quad (4.17)$$

where  $N_C$ ,  $N_T$  is the number of shunt VAR compensators and transformers respectively;  $S_{li}$  and  $S_{li}^{max}$  are the apparent power flow and its maximum limit of  $i^{th}$  line;  $P_{Gi}^{min}, P_{Gi}^{max}$  are the limits on real power generation;  $Q_{Gi}^{min}, Q_{Gi}^{max}$  are the limits on reactive power generation;  $V_{Gi}^{min}, V_{Gi}^{max}$  are the limits on generator bus voltages;  $T_i^{min}, T_i^{max}$  are the limits on transformer taps;  $Q_{Ci}^{min}, Q_{Ci}^{max}$  are the limits on shunt compensator;  $V_{Li}^{min}, V_{Li}^{max}$  are the limits on load bus voltages;

Two equality constraints Eq. (4.5) and Eq. (4.6) are automatically satisfied when the power flow converges to an optimal solution. The generator buses' real power (excluding slack bus), transformer tap ratios, voltage limits, and shunt compensator ranges are considered to control variables that are self-limiting. The remaining inequality constraints require constraint handling techniques.

In OPF, generator reactive power capacities are significant. In recent years, WECSs with complete reactive power capability has become commercially viable [60]. WECS can deliver reactive power in the range of -0.4p.u.to 0.5p.u. The negative sign signifies the generator's ability to absorb. Rooftop SPVS is designed as load buses with zero reactive power. However, because utility-based SPVS have built-in converters, full generator modeling is required due to the converters' dynamic behavior [61]. In this study, the reactive power capabilities of SPVS are assessed between -0.4p.u and 0.5p.u.

### 4.3 Constraint Handling Method

The most commonly used CHM is the penalty method. When a constraint violation occurs, its solution is penalized. Owing to its simplicity and operability, the outcome of this method relying on the penalty, which must be determined by trial and error, leading the fitness value to degrade. This study deployed a new CHM called the SF technique which doesn't require any penalty coefficient.

In this work, the SF technique [62] was employed to solve the MOOPF problem with RESs. The steps followed when comparing two solutions are as follows:

- (1) While comparing two non-feasible solutions, the solution having the smallest constraint violation is selected.
- (2) When two feasible solutions are compared, the one with a better fitness solution is selected.
- (3) When a feasible solution is compared to a non-feasible solution, the feasible solution is selected.

Comparing non-feasible solutions based on constraint violation helps push non-feasible answers into the feasible region while comparing viable solutions based on the fitness value enables solution quality to be improved.

#### 4.4 Integration of WECS, and SPVS

##### 4.4.1 WECS, and SPVS Modeling

*a) WECS Modeling:*

The wind speed at a given geographical area is most likely distributed according to Weibull PDF as given below:

$$f(v) = \left(\frac{k}{c}\right) \left(\frac{v}{c}\right)^{(k-1)} (e)^{\left(\frac{-v}{c}\right)^k}; 0 < v < \infty \quad (4.18)$$

where  $v$  is the wind speed (m/sec);  $k, c$  is the shape, and scale factors respectively.

The PDFs for two different shape and scale factors are given in [63]. The relationship between wind speed and power generation is as follows:

$$P_w(v) = \begin{cases} 0; v < v_{in} \text{ and } v > v_{out} \\ P_{wr} \left(\frac{v-v_{in}}{v_r-v_{in}}\right) & ; v_{in} \leq v_w \leq v_r \\ P_{wr}; v_r < v_w \leq v_{out} \end{cases} \quad (4.19)$$

where  $P_{wr}$  is the rated wind power output;  $v_{in}, v_{out}$ , and  $v_r$  are the cut-in, cut-out, and rated wind speeds (m/sec) respectively;

The probability of obtaining a zero and rated power output is given by the following:

$$f_w(P_w = 0) = 1 - e^{(-\left(\frac{v_{in}}{c}\right)^k)} + e^{(-\left(\frac{v_{out}}{c}\right)^k)} \quad (4.20)$$

$$f_w(P_w = P_{wr}) = e^{(-\left(\frac{v_r}{c}\right)^k)} + e^{(-\left(\frac{v_{out}}{c}\right)^k)} \quad (4.21)$$

The probability for the linear part of the wind speed is given by the following:

$$f_w(P_w) = \left(\frac{k(v_r-v_{in})}{cP_{wr}}\right) \left(\frac{v_{in}P_{wr}+P_w(v_r-v_{in})}{cP_{wr}}\right)^{(k-1)} e^{(-\left(\frac{v_{in}P_{wr}+P_w(v_r-v_{in})}{cP_{wr}}\right)^k)} \quad (4.22)$$

*b) SPVS Modeling:*

Similarly, the power output of a solar PV system (SPVS) is a factor of solar irradiance and it likely follows the Lognormal PDF [64] as follows:

$$f_G(G_S) = \frac{1}{G_S \sigma \sqrt{2\pi}} e^{\frac{-(\ln G_S - \mu)^2}{2\sigma^2}}; G_S > 0 \quad (4.23)$$

where  $\mu$  and  $\sigma$  are the mean and standard deviation respectively;  $G_S$  is the solar irradiance ( $\text{W/m}^2$ ).

The SPVS unit's solar irradiance to energy generation is as follows [65]:

$$P_S(G_S) = \begin{cases} P_{sr} \left( \frac{G_S^2}{G_{std} R_c} \right) & ; 0 < G_S < R_c \\ P_{sr} \left( \frac{G_S}{G_{std}} \right) & ; G_S \geq R_c \end{cases} \quad (4.24)$$

where  $G_{std}$  is the standard solar irradiance ( $\text{W/m}^2$ );  $R_c$  is the particular irradiance point ( $\text{W/m}^2$ );  $P_{sr}$  is the SPVS-rated power output.

#### 4.4.2 Uncertainty cost calculation of WECS, and SPVS

Since WECS and SPVS powers are intermittent, Monte-Carlo simulations were used to account for uncertainty and calculate the uncertainty cost. The estimated cost for the intermittency of WECS and SPVS power is reflected in three ways: direct, reserve, and penalty costs. Whenever power is underestimated, extra unusable power is wasted; however, in practical power system applications, such power can be saved in an energy storage system and thus be counted as the reserve cost. The cost of overestimating power that is lower than the scheduled power is considered a penalty cost in the case of overestimation.

The direct cost associated with  $j^{th}$  WECS is as follows:

$$C_{w,j}(P_{ws,j}) = g_j P_{ws,j} \quad (4.25)$$

Similarly, the direct cost of  $k^{th}$  SPVS is as follows:

$$C_{w,k}(P_{ss,k}) = h_k P_{ss,k} \quad (4.26)$$

where  $P_{ws,j}$ ,  $P_{ss,k}$  are the scheduled powers of  $j^{th}$  WECS,  $k^{th}$  SPVS respectively;  $g_j$ ,  $h_k$  are the direct cost constants of  $j^{th}$  WECS,  $k^{th}$  SPVS respectively;

If the actual output power of the wind farm is lower than the predicted value, to ensure a constant supply of electricity to the consumers, the operator requires some spinning reserve. It is called the overestimation of power from unreliable sources. The cost incurred to maintain the spinning reserve is known as the reserve cost [66].

The reserve cost of the  $j^{th}$  WECS is as follows:

$$C_{Rw,j}(P_{ws,j} - P_{wav,j}) = K_{Rw,j}(P_{ws,j} - P_{wav,j}) = K_{Rw,j} \int_0^{P_{ws,j}} (P_{ws,j} - p_{w,j}) f_w(p_{w,j}) dp_{w,j}$$

(4.27)

In contrast to the overestimation scenario, when the power output of wind exceeds the predicted output, the surplus power generated by WECS cannot be used and is wasted. This is called the underestimation of power from uncertain sources. In this case, ISO must pay a penalty for excess power.

The penalty cost of the  $j^{th}$  WECS is as follows:

$$C_{Pw,j}(P_{wav,j} - P_{ws,j}) = K_{Pw,j}(P_{wav,j} - P_{ws,j}) = K_{Pw,j} \int_{P_{ws,j}}^{P_{wr,j}} (P_{w,j} - p_{ws,j}) f_w(p_{w,j}) dp_{w,j} \quad (4.28)$$

where  $K_{Rw,j}$ ,  $K_{Pw,j}$  are the reserve, penalty cost constants of  $j^{th}$  WECS respectively;  $P_{wr,j}$  and  $P_{wav,j}$  are the rated and actually available powers of  $j^{th}$  WECS;  $f_w(p_{w,j})$  is the possibility of  $j^{th}$  WECS power.

Similarly to WECS, SPVS also exhibits intermittent power output. The SPVS reserve, and penalty cost expressions are provided below [67].

The reserve cost for  $k^{th}$  SPVS plant is as follows:

$$\begin{aligned} C_{Rs,k}(P_{ss,k} - P_{sav,k}) &= K_{Rs,k}(P_{ss,k} - P_{sav,k}) \\ &= K_{Rs,k} * f_s(P_{sav,k} < P_{ss,k}) * [P_{ss,k} - E(P_{sav,k} < P_{ss,k})] \end{aligned} \quad (4.29)$$

The penalty cost for a  $k^{th}$  SPVS plant is as follows:

$$\begin{aligned} C_{Ps,k}(P_{sav,k} - P_{ss,k}) &= K_{Ps,k}(P_{sav,k} - P_{ss,k}) \\ &= K_{Ps,k} * f_s(P_{sav,k} > P_{ss,k}) * [E(P_{sav,k} > P_{ss,k}) - P_{ss,k}] \end{aligned} \quad (4.30)$$

where  $K_{Rs,k}$ ,  $K_{Ps,k}$  are the reserve, penalty cost constants of  $k^{th}$  SPVS respectively;  $P_{sav,k}$  is the actual available power of  $k^{th}$  SPVS;  $f_s(P_{sav,k} < P_{ss,k})$  and  $f_s(P_{sav,k} > P_{ss,k})$  are the probabilities of SPVS power;  $E(P_{sav,k} < P_{ss,k})$ ,  $E(P_{sav,k} > P_{ss,k})$  are the expectations of SPVS power.

## 4.5 Proposed Method

In this chapter, a summation of normalized objective values (SNOV) with improved diversified selection (IDS) is integrated with the multi-objective evolution algorithm based on the decomposition (MOEA/D) [53] to solve the MOOPF problem with RES. The MOEA/D decomposes the multi-objective optimization problem into several single scalar optimization problems and optimizes them all at the same time using weight vectors. The weight vectors' distance is used to create neighborhoods. In every population evolution, information from the neighborhood is used to find a solution. The non-dominated sorting used in MOEA/D is

complex and time-taking. Some useful information may be lost if the dominant solutions are completely discarded. In addition, diversity may be lost during the search process and lead to local optima. To overcome these problems, the summation of normalized objective values with IDS [68] is employed in this work instead of non-dominated sorting selection to get a uniformly distributed Pareto front and improved convergence characteristics.

Proposed algorithm steps:

- 1 Randomly generate the initial population ( $N$ ) and uniformly distributed weights using SSA [54] as given below:

$$N(D, M) = \binom{D + M - 1}{M - 1} \text{ for } D > 0$$

- 2 Run the load flow, and determine the fitness value of the chosen objective function and total constraint violation.

Using angle criteria [55], locate neighbors with the smallest angles for each weight

- 3 vector as given below:

$$\tan \theta = \frac{d_2}{d_1}$$

where  $d_1 = \frac{\|w_i^T w_j\|}{\|w_j\|}$ ,  $d_2 = \left\| w_i - d_1 \frac{w_j}{\|w_j\|} \right\|$

$i, j = 1, 2, \dots, N; i \neq j$ ,  $\theta$  = angle between  $d_1$  and  $d_2$ .

- 4 Evaluate the smaller objective values to form the present ideal point.
- 5 Evaluate the larger objective values to form the present nadir point.
- 6 Angle criteria are used to choose  $N$  pairs of mating parents. A set of mating parents is picked with a probability of  $\delta$  each weight.
- 7 Crossover is used to produce offspring from mated parents. Then, the mutation is applied to produce a new population ( $Q_t$ ).
- 8 The new population is formed by combining the original population ( $P_t$ ) with the new offspring population ( $Q_t$ ).

$$P_t = P_t \cup Q_t$$

- 9 For each objective and solution, calculate the normalized objective values.

- 10 By adding all of the normalized objective values for each solution, obtain the sum of the normalized objective values [68].

For  $m = 1$  to  $M$

Calculate the max and min objectives of the  $m^{th}$  objective and find its range.

Normalize the  $m^{th}$  objective values using the expression:

$$f'_m(x) = \frac{f_m(x) - f_{min}}{f_{max} - f_{min}}$$

End for

For  $i = 1$  to  $N$

Sum up all the normalized objective values to get a unique value

End for

- 11 Calculate the Euclidean space between all of the solutions and the reference point.
- 12 Set a stopping point for the individual with the shortest path to the original point.
- 13 Partition the target range into 100 bins and scan each bin till you reach the stopping point. The solution having the least summation value will be picked to enter into the preferential set for each scanned bin.

- 14 The solutions are dominated by stopping points, and also the individuals who were not selected will be sent to the backup set.
- 15 Apply the fuzzy approach [56] to get the optimal values.

#### 4.6 Results and Discussions

The proposed method was tested on IEEE 57-bus, and 118-bus systems to address the MOOPF problem incorporating WECS and SPVS uncertainties. To consider uncertainties, Monte-Carlo simulations were used to generate 1000 samples. It is programmed in MATLAB R2016a and operates on an i3 processor with 4GB RAM and the results obtained are compared with NSGA-II [57], and MOPSO [58]. The control parameters of the proposed method, NSGA-II, and MOPSO are given in Table 4.1. The various cases considered are given in Table 4.2. The description of the test systems is given in Table 4.3. PDF specifications and cost components of various sources are given in Table 4.4.

**Table 4.1:** Control parameters of the proposed method, NSGA-II, and MOPSO.

#### 4.6.1 IEEE 57-bus system

To test the efficacy of the proposed method, in solving the MOOPF problem the IEEE 57-bus system [59] was considered. It contains 7 thermal generators (# 1 bus as a slack bus), 80 lines, 15 off-nominal transformers, 3 shunt VAR compensators, and real and reactive power demand of 1250.80MW and 336.40MVAR respectively. Notably, the locations of these sources were chosen from [74], by replacing load buses with the respective WECS, and SPVS.

##### a) *Case-1: Minimize $J_1$ and $J_2$ simultaneously*

In this case,  $J_1$ , and  $J_2$  are the objectives that need to be minimized simultaneously. The optimal decision variables obtained by the proposed method are included in Table 4.5. The best-compromised values obtained by the proposed method have a total generation cost of **36195.21\$/h** and emission of **1.0182ton/h**. NSGA-II [57] gives 36399.10\$/h, 1.0912ton/h and MOPSO [58] gives 36733.34\$/h, 1.1145ton/h as shown in Table 4.6. The Pareto-optimal fronts (PFs) observed in this are depicted in Figure 4.1.

##### b) *Case-2: Minimize $J_1$ , $J_2$ and $J_3$ simultaneously*

In this case,  $J_1$ ,  $J_2$ , and  $J_3$  are the objectives that need minimizing simultaneously. The optimal decision variables obtained by the proposed method are included in Table 4.5. The best-compromised values obtained by the proposed method have a total generation cost of **36096.69\$/h**, emission of **1.0238ton/h**, and active power loss of **10.3303MW**. NSGA-II [57] gives 36363.70\$/h, 1.1288ton/h, 10.7953MW and MOPSO [58] gives 39208.74\$/h, 1.0890ton/h, 11.0434MW as shown in Table 4.6. The Pareto-optimal fronts (PFs) observed in this are depicted in Figure 4.1.

##### c) *Case-3: Minimize $J_1$ , $J_2$ , $J_3$ and $J_4$ simultaneously*

In this case,  $J_1$ ,  $J_2$ ,  $J_3$ , and  $J_4$  are the objectives that need to be minimized simultaneously. The optimal decision variables obtained by the proposed method are included in Table 4.5. The best-compromised values obtained by the proposed method have a total generation cost of **36207.21\$/h**, emission of **1.0916ton/h**, active power loss of **9.9732MW**, and voltage magnitude deviation of **0.6848p.u.** NSGA-II [57] gives 36479.38\$/h, 1.1382ton/h,

11.3923MW, 0.8907p.u and MOPSO [58] gives 37321.91\$/h, 1.2049ton/h, 14.5232MW, 0.8323p.u. as shown in Table 4.6.

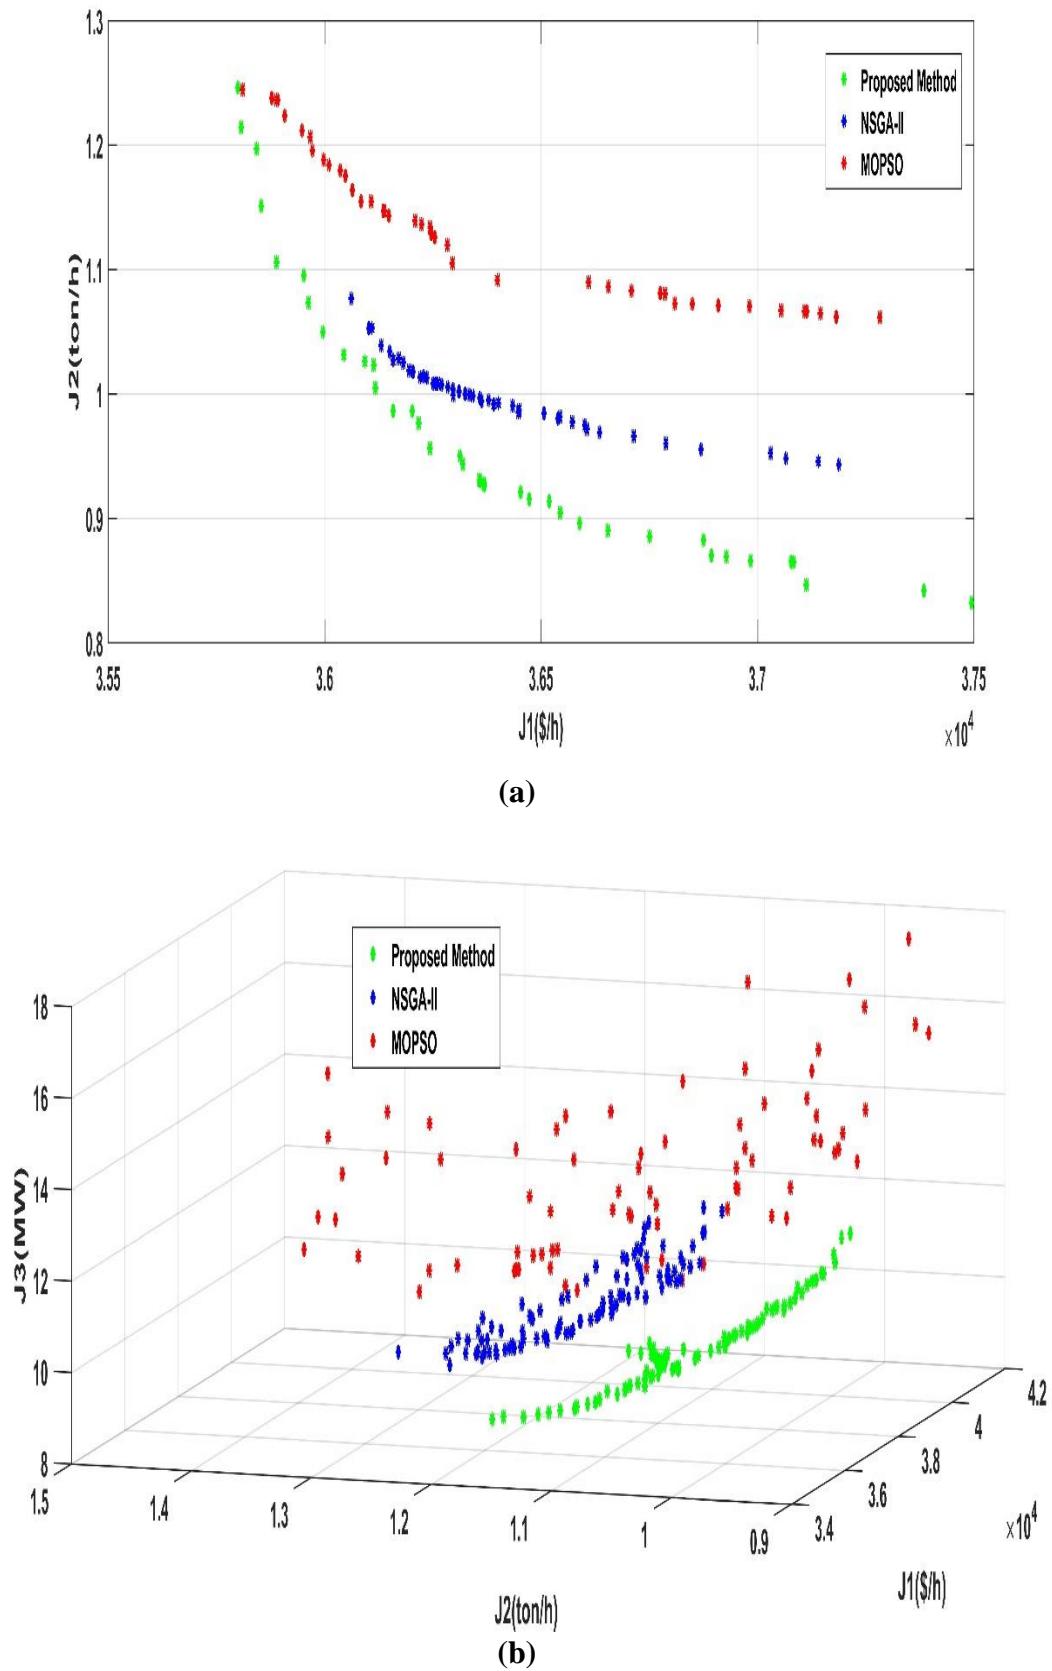

Fig. 4.1: IEEE 57-bus system: Pareto-optimal fronts. a) Case-1, and b) Case-2.

#### 4.6.2 IEEE 118-bus system

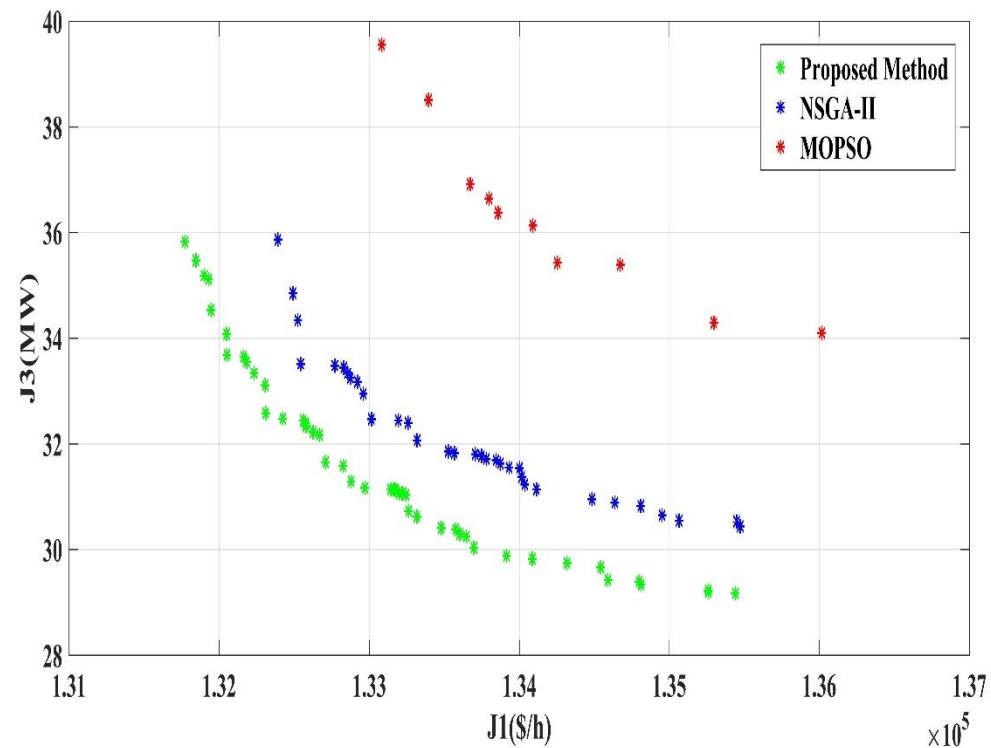

To show the scalability of the proposed method for a large-scale system in solving the MOOPF problem, the IEEE 118-bus system [59] is considered. It contains 54 thermal generators (# 69 bus as a slack bus), 186 lines, 9 off-nominal transformers, and 12 shunt VAR compensators. The real and reactive power demand on the system is 4242.00MW and 1439.00MVAR respectively. Notably, the locations of these sources were chosen from [74], by replacing load buses with the respective WECS, and SPVS.

##### a) Case-4: Minimize $J_1$ and $J_3$ simultaneously

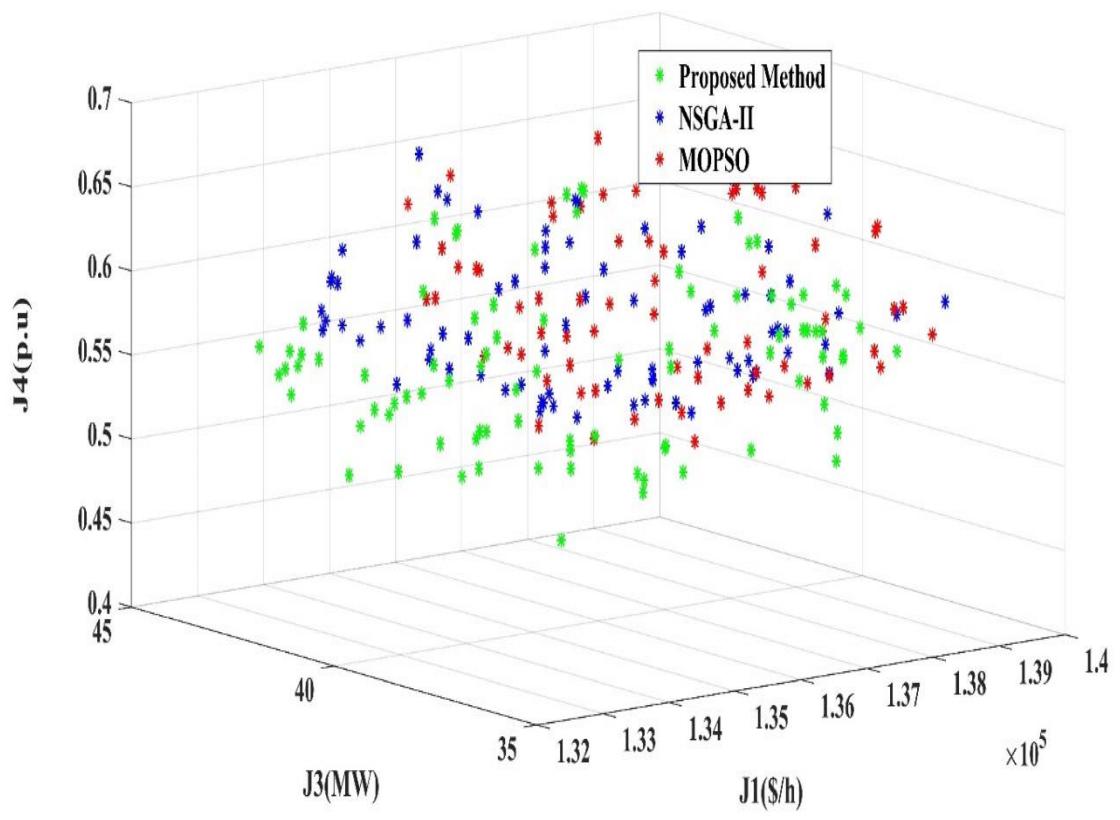

In this case,  $J_1$ , and  $J_3$  are the objectives that need to be minimized simultaneously. The optimal decision variables obtained by the proposed method are included in Table 4.7. The best-compromised values obtained by the proposed method have a total generation cost of **132958.66\$/h**, and an active power loss of **31.2916MW**. NSGA-II [57] gives 133837.90\$/h, 31.8664MW and MOPSO [58] gives 134673.5\$/h, 35.3868MW as shown in Table 4.8. The Pareto-optimal fronts (PFs) observed in this are depicted in Figure 4.2.

##### b) Case-5: Minimize $J_1$ , $J_3$ and $J_4$ simultaneously

In this case,  $J_1$ ,  $J_3$ , and  $J_4$  are the objectives that need minimizing simultaneously. The optimal decision variables obtained by the proposed method are included in Table 4.7. The best-compromised values obtained by the proposed method have a total generation cost of **135774.93\$/h**, active power loss of **39.6333MW**, and voltage magnitude deviation of **0.4299p.u.** NSGA-II [57] gives 135912.8\$/h, 45.6904MW, 0.5074p.u and MOPSO [58] gives 136459.9\$/h, 48.3446MW, 0.5878p.u. as shown in Table 4.8. The Pareto optimal fronts (PFs) observed in this are depicted in Figure 4.2.

#### 4.7 Summary

This work proposes a solution to the MOOPF problem with a combination of thermal, WECS, and SPVS using MOEA based on decomposition and summation of normalized objectives with an improved diversified selection method. Using the superiority of the feasible solution (SF) technique, the method also addresses the restrictions in the MOOPF problem. The generation cost of thermal generators and uncertainty cost associated with WECS and SPVS are minimized along with emission, active power loss, and voltage magnitude deviation. Monte Carlo simulations were used to assess the uncertainty of WECS and SPVS power. To show the efficacy of the proposed method, simulations were done on the IEEE 57-bus and IEEE 118-bus systems, and the results were compared with NSGA-II and MOPSO algorithms. The outcomes show that the proposed method is superior to competing methods. Therefore, the proposed approach can be effectively used in operation and control when WECS and SPVS power generation are included in the power system. This work is limited to the MOOPF problem with integration of WECS, and SPVS, to assess the impact of PEV integration on the MOOPF problem along with WECS, and SPVS next work is proposed.

## Chapter 5

# A New Hybrid Decomposition and Summation of Normalized Objectives with Improved Diversified Selection Based Multi-Objective Evolutionary Algorithm Including Wind, Solar, and PEV Uncertainty for the Optimal Power Flow

### 5.1 Introduction

This chapter presents a new hybrid decomposition and summation of normalized objectives with improved diversified selection-based MOEA for the OPF problem including WECS, SPVS, and PEVs uncertainty with four conflicting objectives including minimizing total generation cost, emission, active power loss, and voltage magnitude deviation. The MOOPF problem was solved using a unique CHM that adaptively inserts the penalty and avoids the parameter relying on penalty calculation. The summation-based sorting and enhanced diverse selection are used to improve the diversity of MOEA. In addition, a fuzzy algorithm is used to determine the optimal compromise values from Pareto-optimal solutions. The impact of intermittence of WECS, SPVS, and PEVS integration was considered for optimal cost analysis. The uncertainty associated with WECS, SPVS, and PEV systems was represented using PDFs and its uncertainty cost is calculated using the Monte-Carlo simulations. To test the effectiveness of the suggested method, IEEE 57-bus and 118-bus systems were assessed, and the acquired results were compared with NSGA-II and MOPSO.

The contributions of this chapter are as follows:

- i. Proposing a novel hybrid MOEA for solving the MOOPF problem based on the decomposition and summation of normalized objectives with an enhanced diverse selection.
- ii. Integrating WECS, SPVS, and PEV systems into the traditional OPF to investigate the effect of the stochastic nature of the sources.
- iii. Modeling uncertainty associated with WECS, SPVS, and PEV systems using PDFs, and evaluating the associated uncertain cost using Monte-Carlo simulations.
- iv. Using an efficient constraint handling method called the SF method to address various constraints in the MOOPF problem.

### 5.2 Problem Formulation

The objectives and constraints for the considered MOOPF problem are expressed as follows:

### 5.2.1 Objectives

The MOOPF problem is formulated using four objectives: minimizing a) total generation cost ( $J_1$ ), b) emission ( $J_2$ ), c) active power loss ( $J_3$ ), and d) voltage magnitude deviation ( $J_4$ ).

*a) Total generation cost (\$/h):*

The overall generating cost is the sum of the generation cost of thermal, WECS, SPVS, and PEV sources and is expressed by the following equation:

$$\begin{aligned}
 \text{Min } J_1 = & \sum_{i=1}^{N_{TG}} (a_i + b_i P_{TGi} + c_i P_{TGi}^2) \\
 & + \sum_{j=1}^{N_{WG}} [C_{w,j}(P_{ws,j}) + C_{Rw,j}(P_{ws,j} - P_{wav,j}) + C_{Pw,j}(P_{wav,j} - P_{ws,j})] \\
 & + \sum_{k=1}^{N_{SG}} [C_{s,k}(P_{ss,k}) + C_{Rs,k}(P_{ss,k} - P_{sav,k}) + C_{Ps,k}(P_{sav,k} - P_{ss,k})] \\
 & + \sum_{n=1}^{N_{PEV}} [C_{pev,n}(P_{pevs,n}) + C_{Rpev,n}(P_{pevs,n} - P_{pevav,n}) + C_{Ppev,n}(P_{pevav,n} \\
 & \quad - P_{pevs,n})]
 \end{aligned} \tag{5.1}$$

where  $N_{TG}$ ,  $N_{WG}$ ,  $N_{SG}$ , and  $N_{PEV}$  are the number of thermal, WECS, SPVS, and PEVS respectively;  $P_{ws,j}$ ,  $P_{ss,k}$ , and  $P_{pevs,n}$  are the scheduled powers of  $j^{th}$  WECS,  $k^{th}$  SPVS, and  $n^{th}$  PEVS respectively;  $P_{wav,j}$ ,  $P_{sav,k}$ , and  $P_{pevav,n}$  are the actual powers of  $j^{th}$  WECS,  $k^{th}$  SPVS, and  $n^{th}$  PEVS respectively;  $P_{TGi}$  is the  $i^{th}$  thermal generator output power;  $a_i, b_i, c_i$  is the  $i^{th}$  thermal generator cost coefficients;

*b) Emission (ton/h):*

The generation of electric power from traditional fossil fuels would result in the emission of hazardous gases into the atmosphere. The following expression describes the total emission from thermal generators:

$$\text{Min } J_2 = \sum_{i=1}^{N_{TG}} (\alpha_i + \beta_i P_{TGi} + \gamma_i P_{TGi}^2 + \delta_i e^{\varepsilon_i P_{TGi}}) \tag{5.2}$$

where  $\alpha_i, \beta_i, \gamma_i, \delta_i, \varepsilon_i$  are the  $i^{th}$  thermal generator emission coefficients;

*c) Active power loss (MW):*

The following equation can be used to express active power loss:

$$\text{Min } J_3 = \sum_{k=1}^{N_L} (G_k (V_i^2 + V_j^2 - 2V_i V_j \cos \theta_{ij})) \tag{5.3}$$

where  $N_L$  is the number of lines;  $\theta_{ij}$  shows the voltage angle between buses  $i$  and  $j$ ;  $G_k$  represents the conductance of branch  $k$ ;  $V_i$ ,  $V_j$  is the voltage magnitudes at  $i^{th}$  and  $j^{th}$  bus respectively.

*d) Voltage magnitude deviation (p.u.):*

The voltage variation is the sum of all voltage variances at load buses in the network relative to the reference voltage. The mathematical expression is as follows:

$$\text{Min } J_4 = \sum_{i=1}^{N_{PQ}} |(V_i - V_{ref})| \quad (5.4)$$

where  $N_{PQ}$  is the number of PQ buses;  $V_{ref}$  is the reference voltage set to 1 p.u.;  $V_i$  is the  $i^{th}$  load bus voltage.

### 5.2.2 Constraints

The MOOPF objectives are subjected to the following equality and inequality constraints.

*a) Equality constraints:*

The equality restrictions are power-balancing equations in which the sum of the generations of the real and reactive powers is equal to their corresponding demands and losses.

- Power flow constraints

The overall demand and losses throughout the system are equal to the total real and reactive power delivered:

$$P_{Gi} - P_{Di} - V_i \sum_{j=1}^{N_B} V_j (G_{ij} \cos \theta_{ij} + B_{ij} \sin \theta_{ij}) = 0; i = 1, 2, \dots, N_B \quad (5.5)$$

$$Q_{Gi} - Q_{Di} - V_i \sum_{j=1}^{N_B} V_j (G_{ij} \sin \theta_{ij} - B_{ij} \cos \theta_{ij}) = 0; i = 1, 2, \dots, N_B \quad (5.6)$$

where  $N_B$  is the number of buses;  $P_{Gi}$ ,  $Q_{Gi}$ , and  $P_{Di}$ ,  $Q_{Di}$  are the real, reactive power generations and demands at the  $i^{th}$  bus, respectively;  $G_{ij}$ ,  $B_{ij}$  is the conductance, susceptance of lines between buses  $i$  and  $j$  respectively;

*b) Inequality constraints:*

The operational limitations on generators, transformers, and shunt devices, as well as the security requirements on lines and load buses, constitute inequality constraints.

- Generator constraints: The boundary limits of real and reactive powers and the voltage magnitude of the generator buses are expressed as follows:

$$P_{TGi}^{\min} \leq P_{TGi} \leq P_{TGi}^{\max}; i = 1, 2, \dots, N_{TG} \quad (5.7)$$

$$P_{WGi}^{\min} \leq P_{WGi} \leq P_{WGi}^{\max}; i = 1, 2, \dots, N_{WG} \quad (5.8)$$

$$P_{SGi}^{\min} \leq P_{SGi} \leq P_{SGi}^{\max}; i = 1, 2, \dots, N_{SG} \quad (5.9)$$

$$P_{PEVGi}^{\min} \leq P_{PEVGi} \leq P_{PEVGi}^{\max}; i = 1, 2, \dots, N_{PEV} \quad (5.10)$$

$$Q_{TGi}^{\min} \leq Q_{TGi} \leq Q_{TGi}^{\max}; i = 1, 2, \dots, N_{TG} \quad (5.11)$$

$$Q_{WGi}^{min} \leq Q_{WGi} \leq Q_{WGi}^{max}; i = 1,2, \dots N_{WG} \quad (5.12)$$

$$Q_{SGi}^{min} \leq Q_{SGi} \leq Q_{SGi}^{max}; i = 1,2, \dots N_{SG} \quad (5.13)$$

$$V_{Gi}^{min} \leq V_{Gi} \leq V_{Gi}^{max}; i = 1,2, \dots N_G \quad (5.14)$$

- Shunt compensator constraints: The following are the boundary values for shunt compensators:

$$Q_{Ci}^{min} \leq Q_{Ci} \leq Q_{Ci}^{max}; i = 1,2, \dots N_C \quad (5.15)$$

- Transformer constraints: The ideal operating limits for tap settings on a transformer are given as follows:

$$T_i^{min} \leq T_i \leq T_i^{max}; i = 1,2, \dots N_T \quad (5.16)$$

- Security constraints: The voltage limits of the load buses and the apparent power value of each transmission line, which can be restricted by its maximum capacity, are given as follows:

$$V_{Li}^{min} \leq V_{Li} \leq V_{Li}^{max}; i = 1,2, \dots N_{PQ} \quad (5.17)$$

$$|S_{li}| \leq S_{li}^{max}; i = 1,2, \dots N_L \quad (5.18)$$

where  $N_C$  and  $N_T$  is the number of shunt compensators and transformers respectively;  $S_{li}$  and  $S_{li}^{max}$  are the apparent power flow and its maximum limit of  $i^{th}$  line;  $P_{Gi}^{min}, P_{Gi}^{max}$  are the limits on real power generation;  $Q_{Gi}^{min}, Q_{Gi}^{max}$  are the limits on reactive power generation;  $V_{Gi}^{min}, V_{Gi}^{max}$  are the limits on generator bus voltages;  $T_i^{min}, T_i^{max}$  are the limits on transformer taps;  $Q_{Ci}^{min}, Q_{Ci}^{max}$  are the limits on shunt compensator;  $V_{Li}^{min}, V_{Li}^{max}$  are the limits on load bus voltages;

Two equality constraints Eq. (5.5) and Eq. (5.6) are automatically satisfied when the power flow converges to an optimal solution. The generator buses' real power (excluding slack bus), transformer tap ratios, voltage limits, and shunt compensator ranges are considered to control variables that are self-limiting. The remaining inequality constraints require constraint handling techniques.

In OPF, generator reactive power capacities are significant. In recent years, WECSs with complete reactive power capability has become commercially viable [60]. WECS can deliver reactive power in the range of -0.4p.u.to 0.5p.u. The negative sign signifies the generator's ability to absorb. Rooftop solar PV is designed as load buses with zero reactive power. However, because utility-based Solar PVs have converters built-in, full generator modeling is required due to the converters' dynamic behavior [61]. In this study, the reactive power capabilities of SPVS are assessed between -0.4p.u and 0.5p.u.

### 5.3 Constraint Handling Method

A proper CHM must be used in conjunction with an evolutionary algorithm to guide the search process toward a globally optimal solution. Among the many CHMs, the most frequently employed is the penalty approach, which involves adding a penalty to the fitness of a non-feasible solution. Despite its simplicity and ease of implementation, this method's performance is highly dependent on the penalty factor, which must be calibrated through trial and error. To tackle this difficulty, in this study, a new parameter-free CHM superiority of feasible solution (SF) is introduced in the study for solving the MOOPF problem.

In [62], Deb introduced the SF method for handling different constraints efficiently. In the SF method, a comparison is drawn between a pair of solutions. When a pair of solutions are compared, the following cases emerge:

- (1) While comparing two non-feasible solutions, the solution having the smallest constraint violation is selected.
- (2) When two feasible solutions are compared, the one with a better fitness solution is selected.
- (3) When a feasible solution is compared to a non-feasible solution, the feasible solution is selected.

Comparing non-feasible solutions based on constraint violation helps push non-feasible answers into the feasible region while comparing viable solutions based on the fitness value enables solution quality to be improved.

### 5.4 Integration of WECS, SPVS, and PEV Systems

#### 5.4.1 WECS, SPVS, and PEV Modeling

In this part, the WECS, SPVS, and PEV systems are integrated into the conventional OPF problem.

##### a) WECS Modeling:

The wind speed at a given geographical area is most likely distributed according to Weibull PDF as given below:

$$f(v) = \left(\frac{k}{c}\right) \left(\frac{v}{c}\right)^{(k-1)} (e)^{\left(\frac{-v}{c}\right)^k}; 0 < v < \infty \quad (5.19)$$

where  $v$  is the wind speed (m/sec);  $k$ , and  $c$  is the shape, and scale factors respectively.

The PDFs for two different shape and scale factors are given in [63]. The relationship between wind speed and power generation is as follows:

$$P_w(v) = \begin{cases} 0; v < v_{in} \text{ and } v > v_{out} \\ P_{wr} \left( \frac{v-v_{in}}{v_r-v_{in}} \right) ; v_{in} \leq v_w \leq v_r \\ P_{wr}; v_r < v_w \leq v_{out} \end{cases} \quad (5.20)$$

where  $P_{wr}$  is the rated wind power;  $v_{in}$ ,  $v_{out}$ ,  $v_r$  are the cut-in, cut-out, and rated wind speeds (m/sec) respectively;

The probability of obtaining a zero and rated power output is given by the following:

$$f_w(P_w = 0) = 1 - e^{-(\frac{v_{in}}{c})^k} + e^{-(\frac{v_{out}}{c})^k} \quad (5.21)$$

$$f_w(P_w = P_{wr}) = e^{-(\frac{v_r}{c})^k} + e^{-(\frac{v_{out}}{c})^k} \quad (5.22)$$

The probability for the linear part of the wind speed is given by the following:

$$f_w(P_w) = \left(\frac{k(v_r - v_{in})}{cP_{wr}}\right) \left(\frac{v_{in}P_{wr} + P_w(v_r - v_{in})}{cP_{wr}}\right)^{(k-1)} e^{-(\frac{v_{in}P_{wr} + P_w(v_r - v_{in})}{cP_{wr}})^k} \quad (5.23)$$

*b) SPVS Modeling:*

Similarly, the power output of a solar energy system is a factor of solar irradiance and it likely follows the Lognormal PDF [64] as follows:

$$f_G(G_s) = \frac{1}{G_s \sigma \sqrt{2\pi}} e^{\frac{-(\ln G_s - \mu)^2}{2\sigma^2}}; G_s > 0 \quad (5.24)$$

where  $\mu$  and  $\sigma$  are the mean and standard deviation respectively;  $G_s$  is the solar irradiance ( $\text{W/m}^2$ ).

The SPVS unit's solar irradiance to energy generation is as follows [65]:

$$P_S(G_s) = \begin{cases} P_{sr} \left( \frac{G_s^2}{G_{std} R_c} \right) & ; 0 < G_s < R_c \\ P_{sr} \left( \frac{G_s}{G_{std}} \right) & ; G_s \geq R_c \end{cases} \quad (5.25)$$

where  $G_{std}$  is the standard solar irradiance ( $\text{W/m}^2$ );  $R_c$  is the particular irradiance point ( $\text{W/m}^2$ );

$P_{sr}$  is the SPVS-rated power output.

*c) PEV Modeling:*

In recent days, public transport electric vehicles ply most of the time during the day and are charged during off-peak periods and so are not suitable for V2G application. Privately-owned PEVs are generally idle most of the time during the day and hence PEVs are suitable for the vehicle-to-grid (V2G) power-fed capability. The availability of electric vehicles as V2G source follows the normal PDF as follows [69]:

$$f_{pev} = \frac{1}{\sqrt{2\pi\varphi^2}} e^{-\frac{(P_{pev} - \mu)^2}{2\varphi^2}} \quad (5.26)$$

where  $\mu$  and  $\varphi$  are the mean and standard deviation of normal PDF respectively;  $P_{pev}$  is the available V2G power;

Here, the PEVs are used as a source of power feeding the grid through suitable infrastructure. The following assumptions are made regarding the use of PEV as a power source.

- All PEVs supply battery power to the power network through DC/AC inverter.
- All PEVs represent one big V2G charging/discharging station.
- V2G system acts as a power source controller.

Depending on the probability of PEVs availability, the direct, reserve, and penalty costs are calculated.

#### 5.4.2 Uncertainty cost calculation of WECS, SPVS, and PEV Systems

Since WECS, SPVS, and PEVS are intermittent, the Monte-Carlo simulations are used to account for uncertainty and to calculate the uncertainty cost. The estimated cost for the intermittency of WECS, SPVS, and PEVS powers is reflected in three ways: direct, reserve, and penalty costs. Whenever power is underestimated, extra unusable power is wasted; however, in practical power system applications, such power can be saved in an energy storage system and thus be counted as the reserve cost. The cost of overestimating power that is lower than the scheduled power is considered a penalty cost in the case of overestimation.

The direct cost associated with  $j^{th}$  WECS is as follows:

$$C_{w,j}(P_{ws,j}) = g_j P_{ws,j} \quad (5.27)$$

The direct cost of  $k^{th}$  SPVS is as follows:

$$C_{w,k}(P_{ss,k}) = h_k P_{ss,k} \quad (5.28)$$

Similarly, the direct cost of  $n^{th}$  PEVS is as follows:

$$C_{pev,n}(P_{pevs,n}) = d_n P_{pevs,n} \quad (5.29)$$

where  $P_{ws,j}$ ,  $P_{ss,k}$ , and  $P_{pevs,n}$  are the scheduled powers of  $j^{th}$  WECS,  $k^{th}$  SPVS, and  $n^{th}$  PEVS respectively;  $g_j$ ,  $h_k$ , and  $d_n$  are the direct cost coefficients of  $j^{th}$  WECS,  $k^{th}$  SPVS, and  $n^{th}$  PEVS respectively;

When the wind farm's actual output falls short of the predicted value, the system operator must maintain a spinning reserve to ensure that consumers receive uninterrupted power. This is called the overestimation of power delivered from uncertain sources and the cost incurred to maintain the spinning reserve is known as reserve cost [66].

The reserve cost of the  $j^{th}$  WECS is as follows:

$$C_{Rw,j}(P_{ws,j} - P_{wav,j}) = K_{Rw,j}(P_{ws,j} - P_{wav,j}) = K_{Rw,j} \int_0^{P_{ws,j}} (P_{ws,j} - p_{w,j}) f_w(p_{w,j}) dp_{w,j} \quad (5.30)$$

In contrast to the overestimation case, when the actual power output of the wind exceeds the predicted output, the surplus power is squandered if it cannot be utilized. As a result, the

ISO is required to pay a penalty fee for excess power. This is referred to as the underestimation of power delivered from uncertain sources.

The penalty cost of the  $j^{th}$  WECS is as follows:

$$C_{Pw,j}(P_{wv,j} - P_{ws,j}) = K_{Pw,j}(P_{wv,j} - P_{ws,j}) = K_{Pw,j} \int_{P_{ws,j}}^{P_{wr,j}} (P_{w,j} - p_{ws,j}) f_w(p_{w,j}) dp_{w,j} \quad (5.31)$$

where  $K_{Rw,j}$ ,  $K_{Pw,j}$  are the reserve, penalty cost coefficients of  $j^{th}$  WECS respectively;  $P_{wr,j}$ ,  $P_{wv,j}$  are the rated, actually available powers of  $j^{th}$  WECS;  $f_w(p_{w,j})$  be the possibility of  $j^{th}$  WECS.

Like the WECS, SPVS power also shows intermittency in output power. The approach to calculating the over and underestimation cost of SPVS is as follows [67].

The reserve cost for  $k^{th}$  SPVS is as follows:

$$\begin{aligned} C_{Rs,k}(P_{ss,k} - P_{sav,k}) &= K_{Rs,k}(P_{ss,k} - P_{sav,k}) \\ &= K_{Rs,k} * f_s(P_{sav,k} < P_{ss,k}) * [P_{ss,k} - E(P_{sav,k} < P_{ss,k})] \end{aligned} \quad (5.32)$$

The penalty cost for a  $k^{th}$  SPVS is as follows:

$$\begin{aligned} C_{Ps,k}(P_{sav,k} - P_{ss,k}) &= K_{Ps,k}(P_{sav,k} - P_{ss,k}) \\ &= K_{Ps,k} * f_s(P_{sav,k} > P_{ss,k}) * [E(P_{sav,k} > P_{ss,k}) - P_{ss,k}] \end{aligned} \quad (5.33)$$

where  $K_{Rs,k}$ ,  $K_{Ps,k}$  is the reserve, penalty cost constants of  $k^{th}$  SPVS respectively;  $P_{sav,k}$  is the actually available power of  $k^{th}$  SPVS;  $f_s(P_{sav,k} < P_{ss,k})$  and  $f_s(P_{sav,k} > P_{ss,k})$  are the probabilities of SPVS power;  $E(P_{sav,k} < P_{ss,k})$ ,  $E(P_{sav,k} > P_{ss,k})$  are the expectations of SPVS power.

Similarly, PEVS also shows intermittency in output power. The approach to calculating the over and underestimation cost of PEVS is as follows [70, 71].

Reserve cost associated with  $n^{th}$  PEV is defined as:

$$\begin{aligned} C_{Rpev,n}(P_{pevs,n} - P_{pevav,n}) &= K_{Rpev,n}(P_{pevs,n} - P_{pevav,n}) \\ &= K_{Rpev,n} \int_0^{P_{pevs,n}} (P_{pevs,n} - p_{pev,n}) f_{pev}(p_{pev,n}) dp_{pev,n} \end{aligned} \quad (5.34)$$

Penalty cost associated with  $n^{th}$  PEV is defined as:

$$\begin{aligned} C_{Ppev,n}(P_{pevav,n} - P_{pevs,n}) &= K_{Ppev,n}(P_{pevav,n} - P_{pevs,n}) \\ &= K_{Ppev,n} \int_{P_{pevs,n}}^{P_{pevav,n}} (p_{pev,n} - P_{pevs,n}) f_{pev}(p_{pev,n}) dp_{pev,n} \end{aligned} \quad (5.35)$$

where  $K_{Rpev,n}$ ,  $K_{Ppev,n}$  is the reserve, penalty cost constants of  $n^{th}$  PEVS respectively;  $P_{pevr,n}$ ,  $P_{pevav,n}$  are the rated, actually available powers of  $n^{th}$  PEVS;  $f_{pev}(p_{pev,n})$  is the  $n^{th}$  PEVS power probability.

## 5.5 Proposed Method

In this chapter, a summation of normalized objective values (SNOV) with improved diversified selection (IDS) is proposed and integrated with the multi-objective evolution algorithm based on the decomposition (MOEA/D) [53] method to solve the MOOPF problem. The MOEA/D method decomposes the multi-objective optimization problem into several single scalar optimization problems and optimizes them all at the same time using weight vectors. The weight vectors' distance is used to create neighborhoods. In every population evolution, information from the neighborhood is used to find a solution. The non-dominated sorting used in MOEA/D is complex and time-taking. Some useful information may be lost if the dominant solutions are completely discarded. In addition, diversity may be lost during the search process and lead to local optima. To overcome these problems, the summation of normalized objective values [68] with IDS is employed in this work instead of non-dominated sorting selection to get a uniformly distributed Pareto front and improved convergence characteristics.

The proposed MOEA comprises initialization, reproduction, investigation of feasible solutions, normalization and selection, and termination phases.

### 1. Initialization:

- Initialize the population ( $P_t$ ) of size 'N'.
- The uniformly distributed weights are produced using SSA in the following manner:

$$N(D, M) = \binom{D + M - 1}{M - 1} \text{ for } D > 0 \quad (5.36)$$

- Run the load flow, and calculate the fitness of the selected objective and total constraint violation.
- Using angle criteria, locate neighbors with the smallest angles for each weight vector [55] as follows:

$$\tan \varphi = \frac{d_2}{d_1}$$

$$\text{where } d_1 = \frac{\|w_i^T \cdot w_j\|}{\|w_j\|} \text{ and } d_2 = \left\| w_i - d_1 \frac{w_j}{\|w_j\|} \right\|$$

$$\text{where } i, j = 1, 2, \dots, N \text{ and } i \neq j \quad (5.37)$$

Where  $w$  indicates the weight vector,  $\varphi$  indicates the angle between  $d_1$  and  $d_2$ .

- Find the smallest objective values to form the present ideal point.
- Find the largest objective values to form the present nadir point.
- Set iteration count=1.

**2. Reproduction:**

- Use an angle criterion to choose N pair of mating parents. A set of mating parents is picked from neighbors with a probability for each weight vector.
- Perform two-point crossover and mutation operations to generate a new population (Qt).
- Calculate the fitness values for the newly generated population (Qt).
- Compute the total constraint violation for the new population (Qt).
- Merge the original population (Pt) and the new population (Qt).

**3. Investigation of feasible solutions:**

- Sort the total population ascending by total constraint violation values.
- Discover feasible solutions.
- If the number of viable solutions is lower than the population (N), move on to **Step 5**.
- If at least N solutions exist in the total population, move on to **Step 4**.

**4. Normalization and selection:**

- Apply the equation below to each objective and solution to determine the normalized objective value[68, 72].

$$f_i''(x^m) = \frac{f_i(x^m) - f_{i,min}}{f_{i,max} - f_{i,min}} \quad (5.38)$$

where  $f_i''(x^m)$  is the normalized value of  $x^m$  for  $i^{th}$  objective,  $f_{i,max}$ ,  $f_{i,min}$  are the  $i^{th}$  objective limits.

- Obtain a summation of the normalized objective values for all solutions [68, 72].

$$F''(x^m) = \sum_{i=1}^M f_i''(x^m) \quad (5.39)$$

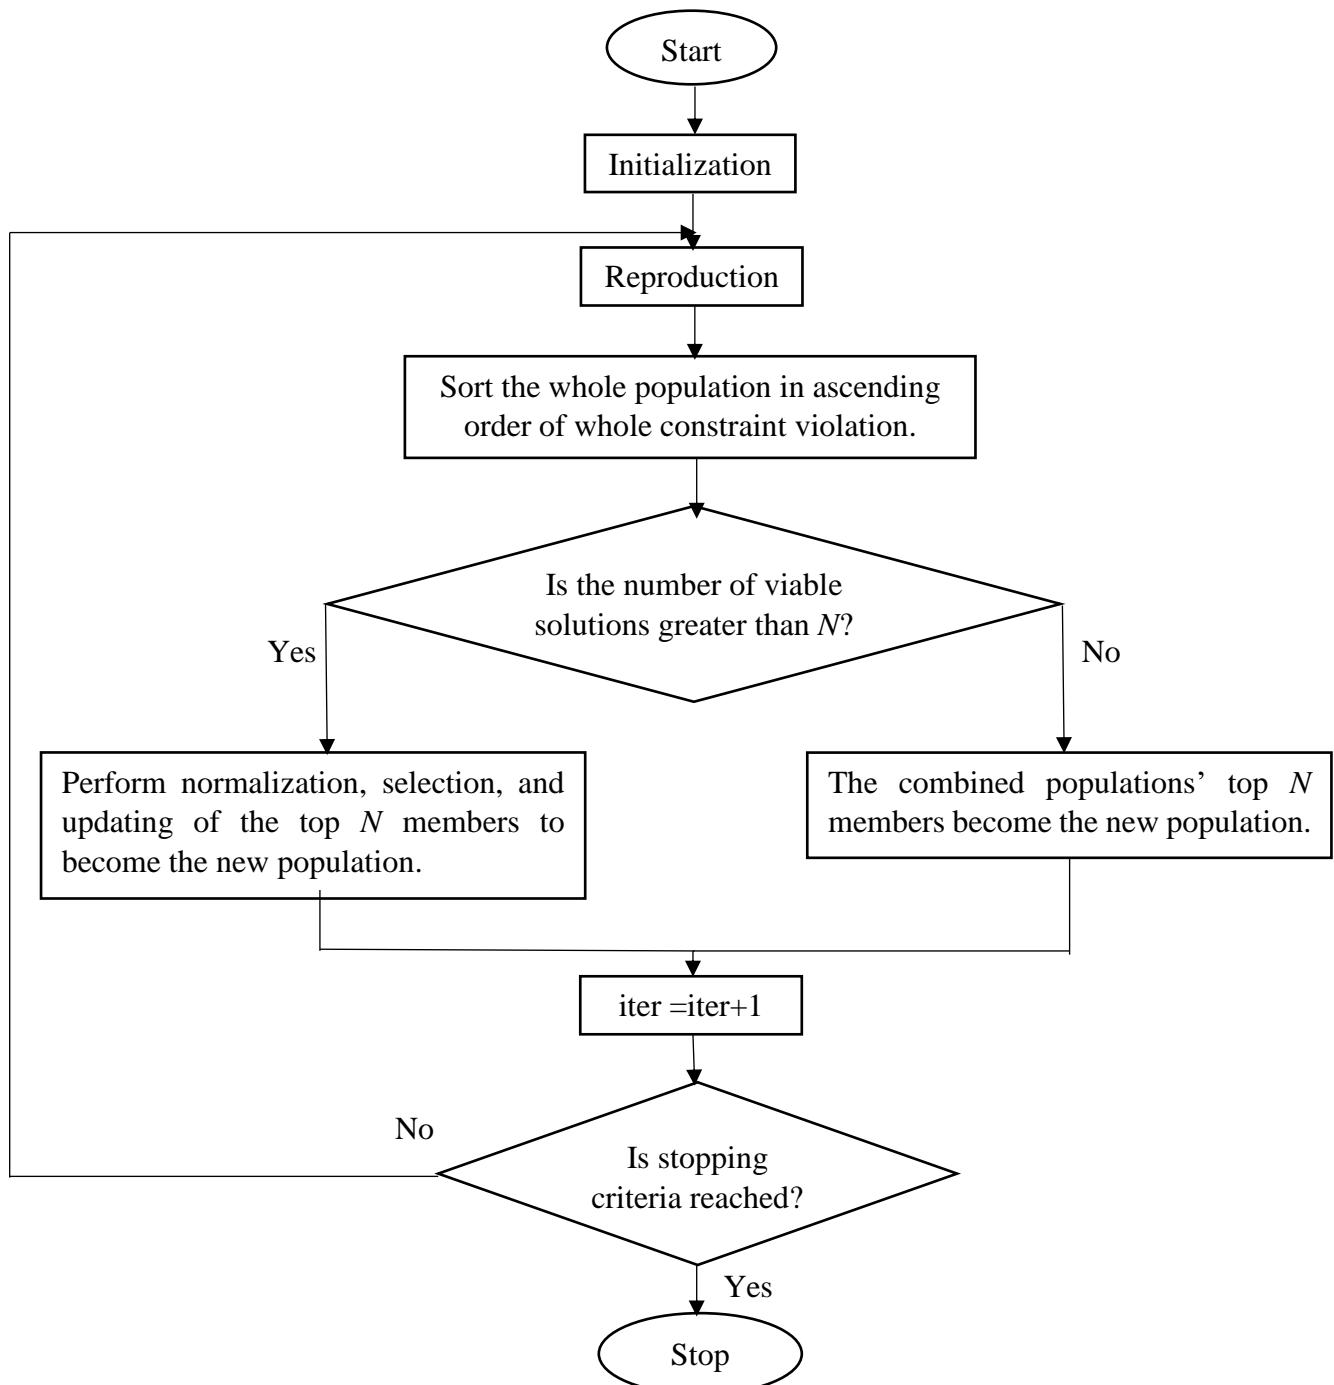

- Calculate the Euclidian distance between the origin and the sum of all normalized objective values. The stopping point is defined by the solution that yields total normalized objective values near to the origin.
- Equally, divide the objective space into 100 bins where scanning of the bins should continue until the scanning procedure reaches a stopping point. For every

scanned bin, the solution with the smallest sum of normalized objective values is entered into the preferred set.

- The backup set includes unselected solutions as well as solutions dominated by the stopping point.

### 5. Termination:

- Increase iteration number by one i.e.  $\text{iter}=\text{iter}+1$ .
- If the stopping requirement is met, Stop else **Go to Step 2**.

**Fig. 5.1:** Flowchart of the proposed method.

## 5.6 Results and Discussions

To analyze the robustness and efficacy of the proposed method, IEEE 57-bus, and 118-bus systems were chosen. The proposed method was implemented in MATLAB R2016a, and simulations were conducted over an i3-Processor having 4 GB RAM. To verify the efficacy of the proposed method, comparisons were made with NSGA-II [57] and MOPSO [58]. In this work, the stochastic nature of WECS, SPVS, and PEV sources was taken into account to study the impact of these sources on the MOOPF problem. To consider uncertainties, Monte-Carlo simulations were used to generate 1000 samples. The control parameters of the proposed method, NSGA-II, and MOPSO are given in Table 5.1. The various cases considered are given in Table 5.2. The description of the test systems is given in Table 5.3. PDF specifications and cost components of various sources are given in Table 5.4.

### 5.6.1 IEEE 57-bus system

The proposed method was tested on an IEEE 57-bus system [59], it has 7 thermal generators (# 1 bus acts as a slack bus), 80 lines, 15 off-nominal transformers, 3 shunt VAR compensators, and real and reactive power demand of 1250.80MW and 336.40MVAR respectively. Notably, the locations of these sources were chosen from [74], by replacing load buses with the respective WECS, SPVS, and PEV sources.

#### a) Case-1: Minimize $J_1$ and $J_2$ simultaneously.

In this case,  $J_1$  and  $J_2$  are the objectives that need to be minimized simultaneously. The optimal decision variables obtained by the proposed method are included in Table 5.5. The best-compromised values obtained using the proposed method have a total generation cost of **35815.04\$/h** and emission of **0.8950ton/h**. The best-compromised values achieved using NSGA-II [57] and MOPSO [58] are 35850.00\$/h, 0.9928ton/h, and 35910.00\$/h, 1.0120ton/h respectively as reported in Table 5.6. The Pareto-optimal fronts (PFs) observed are depicted in Figure 5.2.

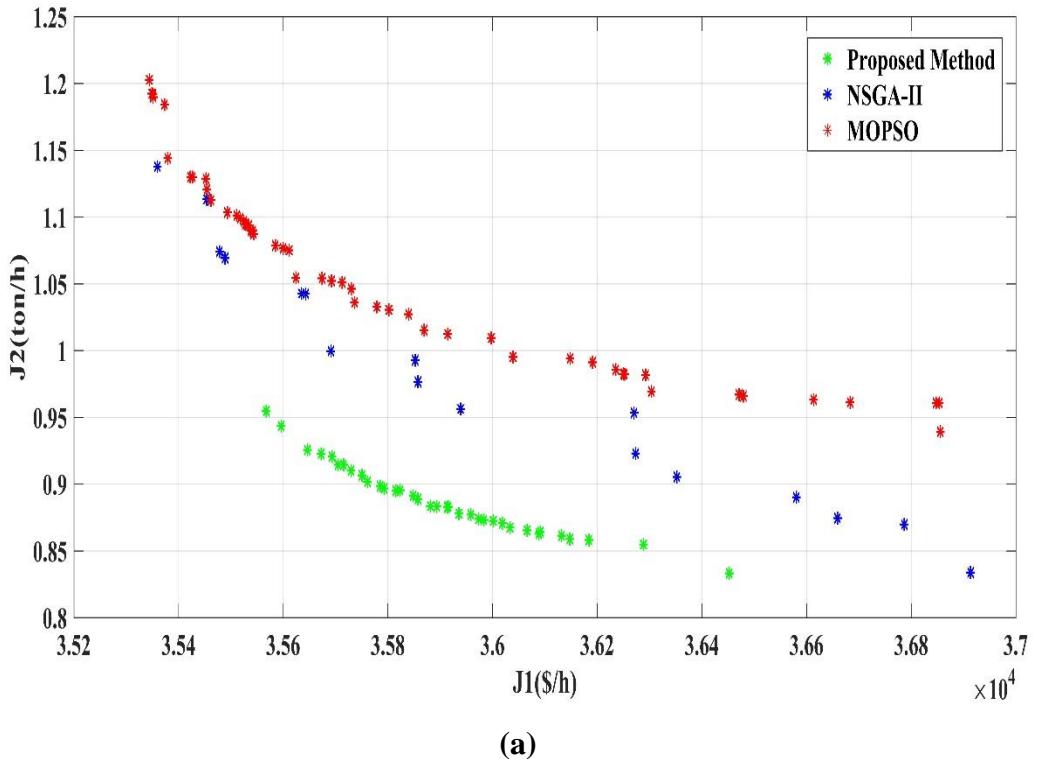

#### b) Case-2: Minimize $J_1$ , $J_2$ and $J_3$ simultaneously.

In this case,  $J_1$ ,  $J_2$ , and  $J_3$  are the objectives that need minimizing simultaneously. The optimal decision variables obtained by the proposed method are included in Table 5.5. The best-compromised values obtained using the proposed method have a total generation cost of **35558.26\$/h**, emission of **0.9673ton/h**, and active power loss of **10.0796MW**. The best compromised values achieved using NSGA-II [57] and MOPSO [58] are 36336.00\$/h, 1.2498ton/h, 11.0813MW and 36402.69\$/h, 1.0450ton/h, 12.5591MW respectively as reported in Table 5.6. The Pareto-optimal fronts (PFs) observed are depicted in Figure 5.2.

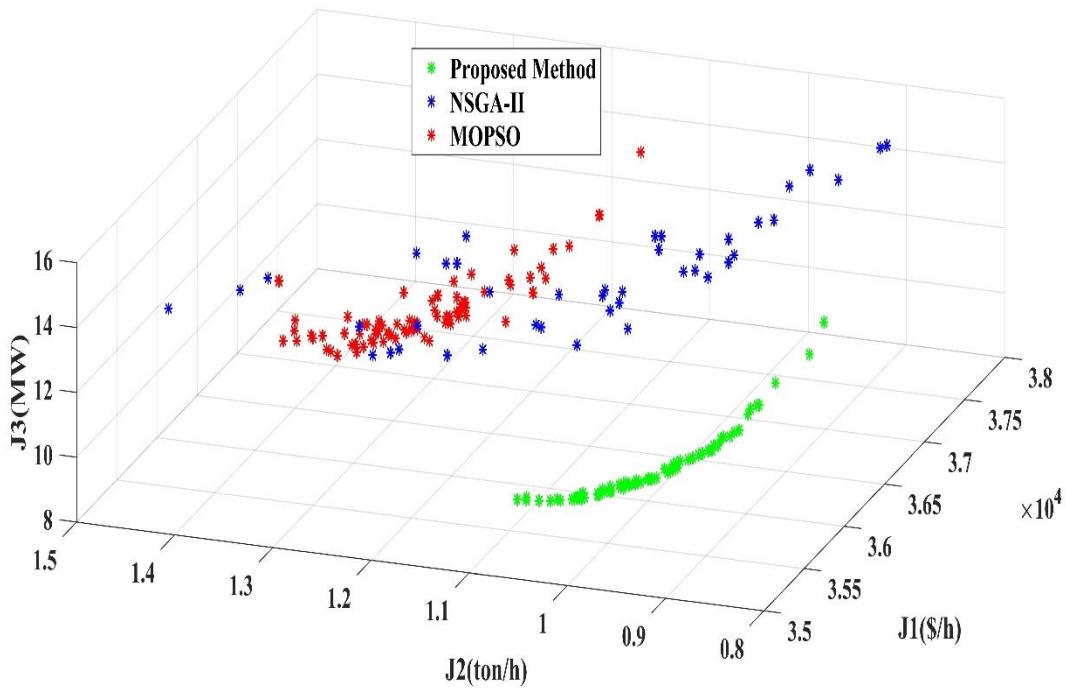

#### c) Case-3: Minimize $J_1$ , $J_2$ , $J_3$ and $J_4$ simultaneously.

In this case,  $J_1$ ,  $J_2$ ,  $J_3$  and  $J_4$  are the objectives that need to be minimized simultaneously. The optimal decision variables obtained by the proposed method are included in Table 5.5. The best-compromised values obtained using the proposed method have a total generation cost of

**35980.02\$/h**, emission of **1.1696ton/h**, active power loss of **10.5229MW**, and voltage magnitude deviation of **0.8308p.u.** The best-compromised values achieved using NSGA-II [57] and MOPSO [58] are 36250.00\$/h, 1.4175ton/h, 12.3871MW, 1.0481p.u. and 36662.59\$/h, 0.9367ton/h, 14.1833MW, 1.0669p.u respectively as reported in Table 5.6.

### 5.6.2 IEEE 118-bus system

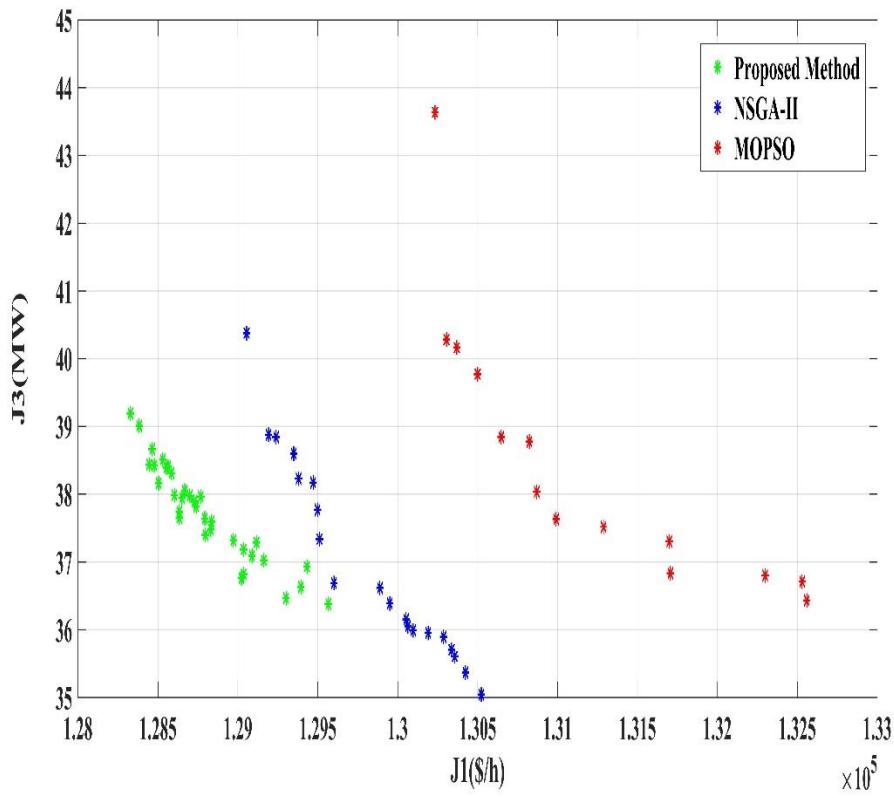

The proposed technique has been examined on an IEEE 118-bus system [59], it has 54 thermal generators (# 69 bus as a slack bus), 186 lines, 9 off-nominal transformers, 12 shunt VAR compensators, and real and reactive power demand of 4242.00 MW and 1439.00 MVAR respectively. Notably, the locations of these sources were chosen from [74], by replacing load buses with the respective WECS, SPVS, and PEV sources.

*a) Case-4: Minimize  $J_1$  and  $J_3$  simultaneously.*

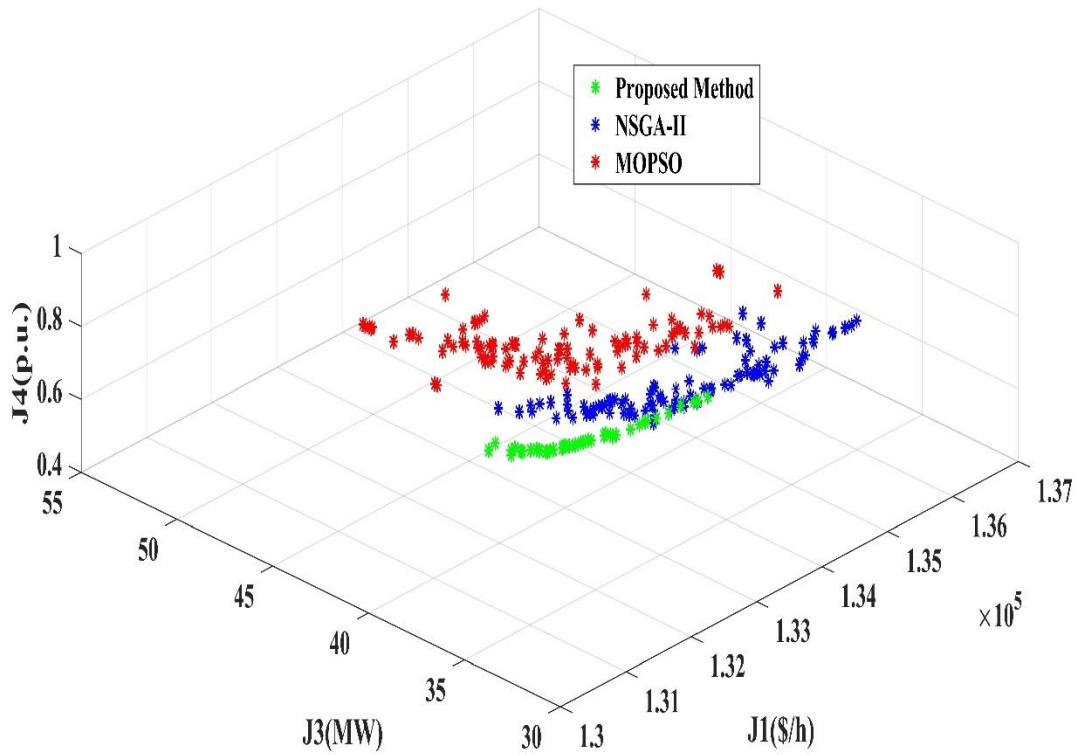

In this case,  $J_1$  and  $J_3$  are the objectives that need to be minimized simultaneously. The optimal decision variables obtained by the proposed method are included in Table 5.7. The best-compromised values obtained using the proposed method have a total generation cost of **129019.12\$/h** and an active power loss of **36.7616MW**. The best-compromised values achieved using NSGA-II [57] and MOPSO [58] are 129582.23\$/h, 37.3464MW, and 130673.5\$/h, 38.0368MW respectively as reported in Table 5.8. The Pareto-optimal fronts (PFs) observed are depicted in Figure 5.3.

*b) Case-5: Minimize  $J_1$ ,  $J_3$  and  $J_4$  simultaneously.*

In this case,  $J_1$ ,  $J_3$ , and  $J_4$  are the objectives that need to be minimized simultaneously. The optimal decision variables obtained by the proposed method are included in Table 5.7. The best-compromised values obtained using the proposed method have a total generation cost of **130796.33\$/h**, active power loss of **32.5358MW**, and voltage magnitude deviation of **0.5165p.u.** The best-compromised values achieved using NSGA-II [57] and MOPSO [58] are 134395.5\$/h, 40.0724MW, 0.6876p.u. and 133574.6\$/h, 41.3020MW, 0.9706p.u. respectively as reported in Table 5.8. The Pareto-optimal fronts (PFs) observed are depicted in Figure 5.3.

## 5.7 Summary

The approach for the MOEA is based on decomposition and summing up normalized objectives with an improved diverse selection mechanism. It also addresses the superiority of the feasible solution (SF) technique for dealing with the MOOPF problem constraints. The cost of thermal energy and the cost uncertainty associated with WECS, SPVS, and PEV systems are minimized along with the minimization of emission, active power loss, and voltage magnitude deviation. Monte Carlo simulations were used to assess the uncertainty of WECS, SPVS, and PEV power. To show the efficacy of the proposed method, simulations were done on the IEEE 57-bus and IEEE 118-bus systems, and the results were compared with NSGA-II and MOPSO algorithms. The outcomes show that the proposed method is superior to competing methods. Therefore, the proposed approach can be effectively used in operation when WECS, SPVS, and PEVS power generations are included in the power system. The proposed method may provide an optimal solution, but to further improve the evolutionary process a new hybrid MOEA is proposed in the next work.

## Chapter 6

### A Novel Hybrid Multi-Objective Evolutionary Algorithm Based on Decomposition and Invasive Weed Optimization Including Wind, Solar, and PEV Uncertainty for the Optimal Power Flow

#### 6.1 Introduction

This chapter proposes a novel hybrid decomposition and invasive weed optimization (IWO) based MOEA for the OPF problem. The standard OPF problem was transformed into a stochastic OPF by incorporating the uncertainty of WECS, SPVS, and PEV systems. This chapter presents a new CHM that adaptively inserts the penalty and avoids the parameter relying on penalty calculation. The IWO technique's selection qualities were utilized to increase the diversity of MOEA. The MOOPF problem includes minimization of the total generation cost, emission, active power loss, and voltage magnitude deviation as objectives. The generation cost of WECS, SPVS, and PEVS was examined using Monte Carlo simulations to reduce the total generation cost. Weibull, Lognormal, and Normal PDFs were used to characterize the unpredictability of WECS, SPVS, and PEVS, respectively. The impact of WECS, SPVS, and PEV uncertainties, was taken into account to validate the proposed method. The superiority of the proposed method was validated by comparing it with NSGA-II, and MOPSO algorithms and tested using IEEE 57-bus and IEEE 118-bus systems.

The contributions of this chapter are as follows:

- i. Introducing a novel hybrid decomposition and invasive weed optimization (IWO) based MOEA for the OPF problem.
- ii. Integrating the stochastic nature of WECS, SPVS, and PEVS with normal OPF to address the influence of the sources' unpredictable nature.
- iii. Modeling the uncertainty of WECS, SPVS, and PEV energy systems using PDF and computing its uncertainty cost with Monte Carlo simulations.
- iv. Using an effective CHM known as the SF method to handle constraints in the MOOPF problem.

#### 6.2 Problem Formulation

The objectives and constraints for the considered MOOPF problem are expressed as follows:

### 6.2.1 Objectives

The MOOPF problem is formulated by considering four objectives which involve minimizing a) total generation cost ( $J_1$ ), b) emission ( $J_2$ ), c) active power loss ( $J_3$ ), and d) voltage magnitude deviation ( $J_4$ ).

*a) Total generation cost (\$/h):*

The overall generating cost is the sum of the generation cost of thermal, WECS, SPVS, and PEV sources and is expressed by the following equation:

$$\begin{aligned}
 \text{Min } J_1 = & \sum_{i=1}^{N_{TG}} (a_i + b_i P_{TG,i} + c_i P_{TG,i}^2) \\
 & + \sum_{j=1}^{N_{WG}} [C_{w,j}(P_{ws,j}) + C_{Rw,j}(P_{ws,j} - P_{wav,j}) + C_{Pw,j}(P_{wav,j} - P_{ws,j})] \\
 & + \sum_{k=1}^{N_{SG}} [C_{s,k}(P_{ss,k}) + C_{Rs,k}(P_{ss,k} - P_{sav,k}) + C_{Ps,k}(P_{sav,k} - P_{ss,k})] \\
 & + \sum_{n=1}^{N_{PEV}} [C_{pev,n}(P_{pevs,n}) + C_{Rpev,n}(P_{pevs,n} - P_{pevav,n}) + C_{Ppev,n}(P_{pevav,n} \\
 & - P_{pevs,n})]
 \end{aligned} \tag{6.1}$$

where  $N_{TG}$ ,  $N_{WG}$ ,  $N_{SG}$ , and  $N_{PEV}$  are the number of thermal, WECS, SPVS, and PEVS respectively;  $P_{ws,j}$ ,  $P_{ss,k}$ , and  $P_{pevs,n}$  are the scheduled powers of  $j^{th}$  WECS,  $k^{th}$  SPVS, and  $n^{th}$  PEVS respectively;  $P_{wav,j}$ ,  $P_{sav,k}$ , and  $P_{pevav,n}$  are the actual powers of  $j^{th}$  WECS,  $k^{th}$  SPVS, and  $n^{th}$  PEVS respectively;  $P_{TG,i}$  is the  $i^{th}$  thermal generator output power;  $a_i, b_i, c_i$  is the  $i^{th}$  thermal generator cost coefficients;

*b) Emission (ton/h):*

The generation of electric power from traditional fossil fuels would result in the emission of hazardous gases into the atmosphere. The following expression describes the total emission from thermal generators:

$$\text{Min } J_2 = \sum_{i=1}^{N_{TG}} (\alpha_i + \beta_i P_{TG,i} + \gamma_i P_{TG,i}^2 + \delta_i e^{\varepsilon_i P_{TG,i}}) \tag{6.2}$$

where  $\alpha_i, \beta_i, \gamma_i, \delta_i, \varepsilon_i$  are the  $i^{th}$  generator emission coefficients;

*c) Active power loss (MW):*

The following equation can be used to express active power loss:

$$\text{Min } J_3 = \sum_{k=1}^{N_L} (G_k (V_i^2 + V_j^2 - 2V_i V_j \cos \theta_{ij})) \tag{6.3}$$

where  $N_L$  is the number of lines;  $\theta_{ij}$  indicates voltage angles between buses  $i$  and  $j$ ;  $G_k$  shows the conductance of branch  $k$ ;  $V_i$ ,  $V_j$  is the voltage magnitudes at  $i^{th}$  and  $j^{th}$  bus respectively.

*d) Voltage magnitude deviation (p.u.):*

The voltage variation is the sum of all voltage variances at load buses in the network relative to the reference voltage. The mathematical expression is as follows:

$$\text{Min } J_4 = \sum_{i=1}^{N_{PQ}} |(V_i - V_{ref})| \quad (6.4)$$

where  $N_{PQ}$  is the number of PQ buses;  $V_{ref}$  is the reference voltage set to 1 p.u.;  $V_i$  is the  $i^{th}$  load bus voltage.

### 6.2.2 Constraints

The MOOPF objectives are subjected to the following equality and inequality constraints.

*a) Equality constraints:*

The equality restrictions are power-balancing equations in which the sum of the generations of the real and reactive powers is equal to their corresponding demands and losses.

- Power flow constraints

The overall demand and losses throughout the system are equal to the total real and reactive power delivered:

$$P_{Gi} - P_{Di} - V_i \sum_{j=1}^{N_B} V_j (G_{ij} \cos \theta_{ij} + B_{ij} \sin \theta_{ij}) = 0; i = 1, 2, \dots, N_B \quad (6.5)$$

$$Q_{Gi} - Q_{Di} - V_i \sum_{j=1}^{N_B} V_j (G_{ij} \sin \theta_{ij} - B_{ij} \cos \theta_{ij}) = 0; i = 1, 2, \dots, N_B \quad (6.6)$$

where  $N_B$  is the number of buses;  $P_{Gi}$ ,  $Q_{Gi}$ , and  $P_{Di}$ ,  $Q_{Di}$  are the real, reactive power generations and demands at the  $i^{th}$  bus, respectively;  $G_{ij}$ ,  $B_{ij}$  is the conductance, susceptance of lines between buses  $i$  and  $j$  respectively;

*b) Inequality constraints:*

The operational limitations on generators, transformers, and shunt devices, as well as the security requirements on lines and load buses, constitute inequality constraints.

- Generator constraints: The boundary limits of real and reactive powers and the voltage magnitude of the generator buses are expressed as follows:

$$P_{TGi}^{\min} \leq P_{TGi} \leq P_{TGi}^{\max}; i = 1, 2, \dots, N_{TG} \quad (6.7)$$

$$P_{WGi}^{\min} \leq P_{WGi} \leq P_{WGi}^{\max}; i = 1, 2, \dots, N_{WG} \quad (6.8)$$

$$P_{SGi}^{\min} \leq P_{SGi} \leq P_{SGi}^{\max}; i = 1, 2, \dots, N_{SG} \quad (6.9)$$

$$P_{PEVGi}^{\min} \leq P_{PEVGi} \leq P_{PEVGi}^{\max}; i = 1, 2, \dots, N_{PEV} \quad (6.10)$$

$$Q_{TGi}^{\min} \leq Q_{TGi} \leq Q_{TGi}^{\max}; i = 1, 2, \dots, N_{TG} \quad (6.11)$$

$$Q_{WGi}^{\min} \leq Q_{WGi} \leq Q_{WGi}^{\max}; i = 1, 2, \dots, N_{WG} \quad (6.12)$$

$$Q_{SGi}^{min} \leq Q_{SGi} \leq Q_{SGi}^{max}; i = 1, 2, \dots, N_{SG} \quad (6.13)$$

$$V_{Gi}^{min} \leq V_{Gi} \leq V_{Gi}^{max}; i = 1, 2, \dots, N_G \quad (6.14)$$

- Shunt VAR compensator constraints: The following are the boundary values for shunt compensators:

$$Q_{Ci}^{min} \leq Q_{Ci} \leq Q_{Ci}^{max}; i = 1, 2, \dots, N_C \quad (6.15)$$

- Transformer constraints: The ideal operating limits for tap settings on a transformer are given as follows:

$$T_i^{min} \leq T_i \leq T_i^{max}; i = 1, 2, \dots, N_T \quad (6.16)$$

- Security constraints: The voltage limits of the load buses and the apparent power value of each transmission line, which can be restricted by its maximum capacity, are given as follows:

$$V_{Li}^{min} \leq V_{Li} \leq V_{Li}^{max}; i = 1, 2, \dots, N_{PQ} \quad (6.17)$$

$$|S_{li}| \leq S_{li}^{max}; i = 1, 2, \dots, N_L \quad (6.18)$$

where  $N_C$  and  $N_T$  is the number of shunt compensators and transformers respectively;  $S_{li}$  and  $S_{li}^{max}$  are the apparent power flow and its maximum limit of  $i^{th}$  line;  $P_{Gi}^{min}, P_{Gi}^{max}$  are the real power generation limits;  $Q_{Gi}^{min}, Q_{Gi}^{max}$  are the reactive power generation limits;  $V_{Gi}^{min}, V_{Gi}^{max}$  are the generator bus voltage limits;  $T_i^{min}, T_i^{max}$  are the transformer tap limits;  $Q_{Ci}^{min}, Q_{Ci}^{max}$  are the shunt compensator limits;  $V_{Li}^{min}, V_{Li}^{max}$  are the load bus voltage limits;

Two equality constraints Eq. (6.5) and Eq. (6.6) are automatically satisfied when the power flow converges to an optimal solution. The generator buses' real power (excluding slack bus), transformer tap ratios, voltage limits, and shunt compensator ranges are considered to control variables that are self-limiting. The remaining inequality constraints require constraint handling techniques.

In OPF, generator reactive power capacities are significant. In recent years, WECSs with complete reactive power capability has become commercially viable [60]. WECS can deliver reactive power in the range of -0.4p.u.to 0.5p.u. The negative sign signifies the generator's ability to absorb. Rooftop solar PV is designed as load buses with zero reactive power. However, because utility-based Solar PVs have built-in converters, full generator modeling is required due to the converters' dynamic behavior [61]. In this study, the reactive power capabilities of SPVS are assessed between -0.4p.u and 0.5p.u.

### 6.3 Constraint Handling Method

Since MOOPF is a constrained optimization problem, it requires a better-constrained handling method. In this work, the SF technique [62] was employed to solve the MOOPF problem with RESs. The steps followed when comparing two solutions are as follows:

- 1) While comparing two non-feasible solutions, the solution having the smallest constraint violation is selected.
- 2) When two feasible solutions are compared, the one with a better fitness solution is selected.
- 3) When a feasible solution is compared to a non-feasible solution, the feasible solution is selected.

Comparing non-feasible solutions based on constraint violation helps push non-feasible answers into the feasible region while comparing viable solutions based on the fitness value enables solution quality to be improved.

### 6.4 Integration of WECS, SPVS, and PEV Sources

#### 6.4.1 WECS, SPVS, and PEV Modeling

a) *WECS Modeling:*

The wind speed at a given geographical area is most likely distributed according to Weibull PDF as given below:

$$f(v) = \left(\frac{k}{c}\right) \left(\frac{v}{c}\right)^{(k-1)} (e)^{\left(\frac{-v}{c}\right)^k}; 0 < v < \infty \quad (6.19)$$

where  $v$  is the wind speed (m/sec);  $k$ , and  $c$  is the shape, and scale factors respectively.

The PDFs for two different shape and scale factors are given in [63]. The relationship between wind speed and power generation is as follows:

$$P_w(v) = \begin{cases} 0; v < v_{in} \text{ and } v > v_{out} \\ P_{wr} \left(\frac{v-v_{in}}{v_r-v_{in}}\right) & ; v_{in} \leq v_w \leq v_r \\ P_{wr}; v_r < v_w \leq v_{out} \end{cases} \quad (6.20)$$

where  $P_{wr}$  is the rated wind power;  $v_{in}$ ,  $v_{out}$ ,  $v_r$  are the cut-in, cut-out, and rated wind speeds (m/sec) respectively;

The probability of obtaining a zero and rated power output is given by the following:

$$f_w(P_w = 0) = 1 - e^{(-\left(\frac{v_{in}}{c}\right)^k)} + e^{(-\left(\frac{v_{out}}{c}\right)^k)} \quad (6.21)$$

$$f_w(P_w = P_{wr}) = e^{(-\left(\frac{v_r}{c}\right)^k)} + e^{(-\left(\frac{v_{out}}{c}\right)^k)} \quad (6.22)$$

The probability for the linear part of the wind speed is given by the following:

$$f_w(P_w) = \left(\frac{k(v_r-v_{in})}{cP_{wr}}\right) \left(\frac{v_{in}P_{wr}+P_w(v_r-v_{in})}{cP_{wr}}\right)^{(k-1)} e^{(-\left(\frac{v_{in}P_{wr}+P_w(v_r-v_{in})}{cP_{wr}}\right)^k)} \quad (6.23)$$

*b) SPVS Modeling:*

Similarly, the power output of an SPVS is a factor of solar irradiance and it likely follows the Lognormal PDF [64] as follows:

$$f_G(G_S) = \frac{1}{G_S \sigma \sqrt{2\pi}} e^{\left\{ \frac{-(\ln G_S - \mu)^2}{2\sigma^2} \right\}}; G_S > 0 \quad (6.24)$$

where  $\mu$  and  $\sigma$  are the mean and standard deviation respectively;  $G_S$  is the solar irradiance ( $\text{W/m}^2$ ).

The SPVS unit's solar irradiance to energy generation is as follows [65]:

$$P_S(G_S) = \begin{cases} P_{sr} \left( \frac{G_S^2}{G_{std} R_c} \right) & ; 0 < G_S < R_c \\ P_{sr} \left( \frac{G_S}{G_{std}} \right) & ; G_S \geq R_c \end{cases} \quad (6.25)$$

where  $G_{std}$  is the standard solar irradiance ( $\text{W/m}^2$ );  $R_c$  is the particular irradiance point ( $\text{W/m}^2$ );  $P_{sr}$  is the SPVS-rated power output.

*c) PEV Modeling:*

In recent days, public transport electric vehicles ply most of the time during the day and are charged during off-peak periods and so are not suitable for V2G application. Privately-owned PEVs are generally idle most of the time during the day and hence PEVs are suitable for the vehicle-to-grid (V2G) power-fed capability. The availability of electric vehicles as V2G source follows the normal PDF as follows [69]:

$$f_{pev} = \frac{1}{\sqrt{2\pi\varphi^2}} e^{-\left\{ \frac{(P_{pev} - \mu)^2}{2\varphi^2} \right\}} \quad (6.26)$$

where  $\mu$  and  $\varphi$  are the mean and standard deviation of normal PDF respectively;  $P_{pev}$  is the available V2G power;

Here, the PEVs are used as a source of power feeding the grid through suitable infrastructure. The following assumptions are made regarding the use of PEV as a power source.

- All PEVs supply battery power to the power network through DC/AC inverter.
- All PEVs represent one big V2G charging/discharging station.
- V2G system acts as a power source controller.

Depending on the probability of PEVs availability, the direct, reserve, and penalty costs are calculated

#### 6.4.2 Uncertainty cost calculation of WECS, SPVS, and PEV Sources

Since WECS, SPVS, and PEVS are intermittent, the Monte Carlo simulations are used to account for uncertainty and to calculate the uncertainty cost. The estimated cost for the

intermittency of WECS, SPVS, and PEVS powers is reflected in three ways: direct, reserve, and penalty costs. Whenever power is underestimated, extra unusable power is wasted; however, in practical power system applications, such power can be saved in an energy storage system and thus be counted as the reserve cost. The cost of overestimating power that is lower than the scheduled power is considered a penalty cost in the case of overestimation.

The direct cost of  $j^{th}$  WECS is as follows:

$$C_{w,j}(P_{ws,j}) = g_j P_{ws,j} \quad (6.27)$$

The direct cost of  $k^{th}$  SPVS is as follows:

$$C_{w,k}(P_{ss,k}) = h_k P_{ss,k} \quad (6.28)$$

The direct cost of  $n^{th}$  PEV unit is as follows:

$$C_{pev,n}(P_{pevs,n}) = d_n P_{pevs,n} \quad (6.29)$$

where  $P_{ws,j}$ ,  $P_{ss,k}$ , and  $P_{pevs,n}$  are the scheduled powers of  $j^{th}$  WECS,  $k^{th}$  SPVS, and  $n^{th}$  PEVS respectively;  $g_j$ ,  $h_k$ , and  $d_n$  are the direct cost coefficients of  $j^{th}$  WECS,  $k^{th}$  SPVS, and  $n^{th}$  PEV systems respectively;

The approach to calculating the over and underestimation cost of WECS is as follows [66].

The reserve cost of the  $j^{th}$  WECS is as follows:

$$C_{Rw,j}(P_{ws,j} - P_{wav,j}) = K_{Rw,j}(P_{ws,j} - P_{wav,j}) = K_{Rw,j} \int_0^{P_{ws,j}} (P_{ws,j} - p_{w,j}) f_w(p_{w,j}) dp_{w,j} \quad (6.30)$$

The penalty cost of the  $j^{th}$  WECS is as follows:

$$C_{Pw,j}(P_{wav,j} - P_{ws,j}) = K_{Pw,j}(P_{wav,j} - P_{ws,j}) = K_{Pw,j} \int_{P_{ws,j}}^{P_{wr,j}} (P_{w,j} - p_{ws,j}) f_w(p_{w,j}) dp_{w,j} \quad (6.31)$$

where  $K_{Rw,j}$  and  $K_{Pw,j}$  are the reserve and penalty cost coefficients of  $j^{th}$  WECS respectively;  $P_{wr,j}$  and  $P_{wav,j}$  are rated and actually available powers of  $j^{th}$  WECS;  $f_w(p_{w,j})$  be the possibility of  $j^{th}$  WECS.

The approach to calculating the over and underestimation cost of SPVS is as follows [67].

The reserve cost for  $k^{th}$  SPVS is as follows:

$$\begin{aligned} C_{Rs,k}(P_{ss,k} - P_{sav,k}) &= K_{Rs,k}(P_{ss,k} - P_{sav,k}) \\ &= K_{Rs,k} * f_s(P_{sav,k} < P_{ss,k}) * [P_{ss,k} - E(P_{sav,k} < P_{ss,k})] \end{aligned} \quad (6.32)$$

The penalty cost for a  $k^{th}$  SPVS is as follows:

$$\begin{aligned} C_{PS,k}(P_{sav,k} - P_{ss,k}) &= K_{PS,k}(P_{sav,k} - P_{ss,k}) \\ &= K_{PS,k} * f_s(P_{sav,k} > P_{ss,k}) * [E(P_{sav,k} > P_{ss,k}) - P_{ss,k}] \end{aligned} \quad (6.33)$$

where  $K_{RS,k}$  and  $K_{PS,k}$  are the reserve and penalty cost constants of  $k^{th}$  SPVS respectively;  $P_{sav,k}$  is the actual available power of  $k^{th}$  SPVS;  $f_s(P_{sav,k} < P_{ss,k})$  and  $f_s(P_{sav,k} > P_{ss,k})$  are the probabilities of SPVS power;  $E(P_{sav,k} < P_{ss,k})$ ,  $E(P_{sav,k} > P_{ss,k})$  are the expectations of SPVS power.

The approach to calculating the over and underestimation cost of PEVS is as follows [70, 71].

Reserve cost associated with  $n^{th}$  PEV is defined as:

$$\begin{aligned} C_{Rpev,n}(P_{pevs,n} - P_{pevav,n}) &= K_{Rpev,n}(P_{pevs,n} - P_{pevav,n}) \\ &= K_{Rpev,n} \int_0^{P_{pevs,n}} (P_{pevs,n} - p_{pev,n}) f_{pev}(p_{pev,n}) dp_{pev,n} \end{aligned} \quad (6.34)$$

Penalty cost associated with  $n^{th}$  PEVS is defined as:

$$\begin{aligned} C_{Ppev,n}(P_{pevav,n} - P_{pevs,n}) &= K_{Ppev,n}(P_{pevav,n} - P_{pevs,n}) \\ &= K_{Ppev,n} \int_{P_{pevs,n}}^{P_{pevav,n}} (p_{pev,n} - P_{pevs,n}) f_{pev}(p_{pev,n}) dp_{pev,n} \end{aligned} \quad (6.35)$$

where  $K_{Rpev,n}$  and  $K_{Ppev,n}$  are the reserve and penalty cost constants of  $n^{th}$  PEVS respectively;  $P_{pevr,n}$  and  $P_{pevav,n}$  are the rated and actually available powers of  $n^{th}$  PEVS;  $f_{pev}(p_{pev,n})$  is the  $n^{th}$  PEVS power probability.  $f_{pev}(p_{pev,n})$  is the  $n^{th}$  PEVS power probability.

## 6.5 Proposed Method

In this chapter, the modified IWO [73] for multi-objective optimization and then include in MOEA/D [53], which provides a decomposition-based multi-objective optimization method with invasive weed colonies, to merge their exceptional qualities in the proposed hybrid method. The flowchart of the proposed method is shown in Figure 6.1.

The proposed method decomposes a multi-objective issue into a large number of scalar optimization sub-problems and solves them simultaneously. In each sub-problem, an adaptive IWO search was used to minimize the aggregation function of all objectives under consideration. Each sub-problem has a unique aggregation weight that generates a distinct aggregation function from those of others. The population size at each generation is equal to the number of decomposed sub-problems. If  $N$  is specified as the population size, then  $N$  sub-problems must be simultaneously optimized. The objective function of  $i^{th}$  sub-problem can be expressed as follows.

$$g^{te}(x|\lambda^i, z^*) = \max\{\lambda_j^i | f_j(x) - z_j^*|\}; 1 \leq j \leq m \quad (6.36)$$

Where  $\lambda^i = (\lambda_1^i, \lambda_2^i, \dots, \lambda_m^i)^T$ ,  $m$  is the number of objectives and  $z^* = (z_1^*, z_2^*, \dots, z_m^*)^T$ ,  $z_i^* = \min\{f_i(x) | x \in [l, u]\}$ ,  $i = 1, 2, \dots, m$  is the point of reference.

The proposed method steps are as follows:

**Input:**  $N$ : population size;

$T$ : neighborhood size,  $0 < T < N$ ;

$\lambda^1, \lambda^2, \dots, \lambda^N$ : weight vectors;

**Output:** PO solutions;

1. Initialization:
2.  $x^1, x^2, \dots, x^N$  is randomly selected between  $[l, u]$        $FV^j = F(x^j)$ ;
3.      For each  $j = 1:N$  do  $neb(j) = \{a, b, \dots, t\}$ ;
4.      reference point  $z = (z_1, z_2, \dots, z_m)^T$ .
5. Do while (loop is not met)
6.      For  $j = 1:N$
7.           $U \leftarrow IWO(x^j, std_{iter}^j)$ ;
8.           $V \leftarrow IWO(x^k, std_{iter}^k)$ ;  
            /  $k$  is chosen from  $neb(j)$  /
9.          For each  $y \in U \cup V$  do
10.           If  $y \notin [l, u]$  then
11.               $y$  repair ( $y$ );
12.           End
13.           For each  $i = 1$  to  $m$  do
14.              If  $z_i > f_i(y)$  then
15.                    $z_i = f_i(y)$ ;
16.              End
17.           End
18.           For each  $i \in neb(j)$  do
19.              If  $g^{te}(y|\lambda^i, z) < g^{te}(x^i|\lambda^i, z)$  then
20.                    $x^i = y$ ;
21.                    $FV^i = F(y)$ ;
22.              End
23.           End
24.          End
25.      End
26. End Do
27. Use fuzzy theory to get best-compromised values [55].

In line 7 of the pseudo-code,  $U \leftarrow IWO(x^i, std_{iter}^i)$  expresses the procedure of producing  $x^i$  seeds.  $U$  Contains the children's seeds generated by  $x^i$ . Suppose  $U = \{y^1, y^2, \dots, y^k\}$ ; then  $k$  is the size of children seeds generated by  $x^i$ , which is calculated using Eq. (6.37).

$$S_{num} = \text{floor} \left( \frac{g_{max}^{te} - g_{min}^{te}}{g_{max}^{te} - g_{min}^{te}} (S_{max} - S_{min}) + S_{min} \right) \quad (6.37)$$

where  $g_{min}^{te}$ ,  $g_{max}^{te}$  are obtained as follows:

$$g_{min}^{te} = \min\{g^{te}(x^k|\lambda^i, z^*) | x^k \in B(i)\} \quad (6.38)$$

$$g_{max}^{te} = \max\{g^{te}(x^k | \lambda^i, z^*) | x^k \in B(i)\} \quad (6.39)$$

where  $std_{iter}^i$  represents the adaptive standard deviation (SD) of  $x^i$  and its value can be obtained through Eq. (6.40) and Eq. (6.41).

$$\sigma_{iter} = \sigma_{final} + \left( \frac{iter_{max} - iter}{iter_{max}} \right)^{pow} \cdot (\sigma_{initial} - \sigma_{final}) \quad (6.40)$$

It is evident from Eq. (6.40) that  $\sigma_{iter}$  reduces with increasing iterations. However, for each parent seed in a single generation, the value  $\sigma_{iter}$  remains constant. This does not promote exploration or efficient exploration. Each parent should have weed characteristics that are distinct from those of other parents. In this study, an adaptive standard deviation (SD)  $std_{iter}$  was employed, whose  $\sigma_{iter}$  value fluctuates with iteration and rank. The SD can be characterized as follows:

$$std_{iter} = \begin{cases} \left( 1 + Q \frac{g^{te} - g_{mean}^{te}}{g_{max}^{te} - g_{mean}^{te}} \right) * \sigma_{iter}; & g^{te} \geq g_{mean}^{te} \\ \left( 1 - Q \frac{g_{mean}^{te} - g^{te}}{g_{mean}^{te} - g_{min}^{te}} \right) * \sigma_{iter}; & otherwise \end{cases} \quad (6.41)$$

Where  $g_{mean}^{te}$  is formulated as follows:

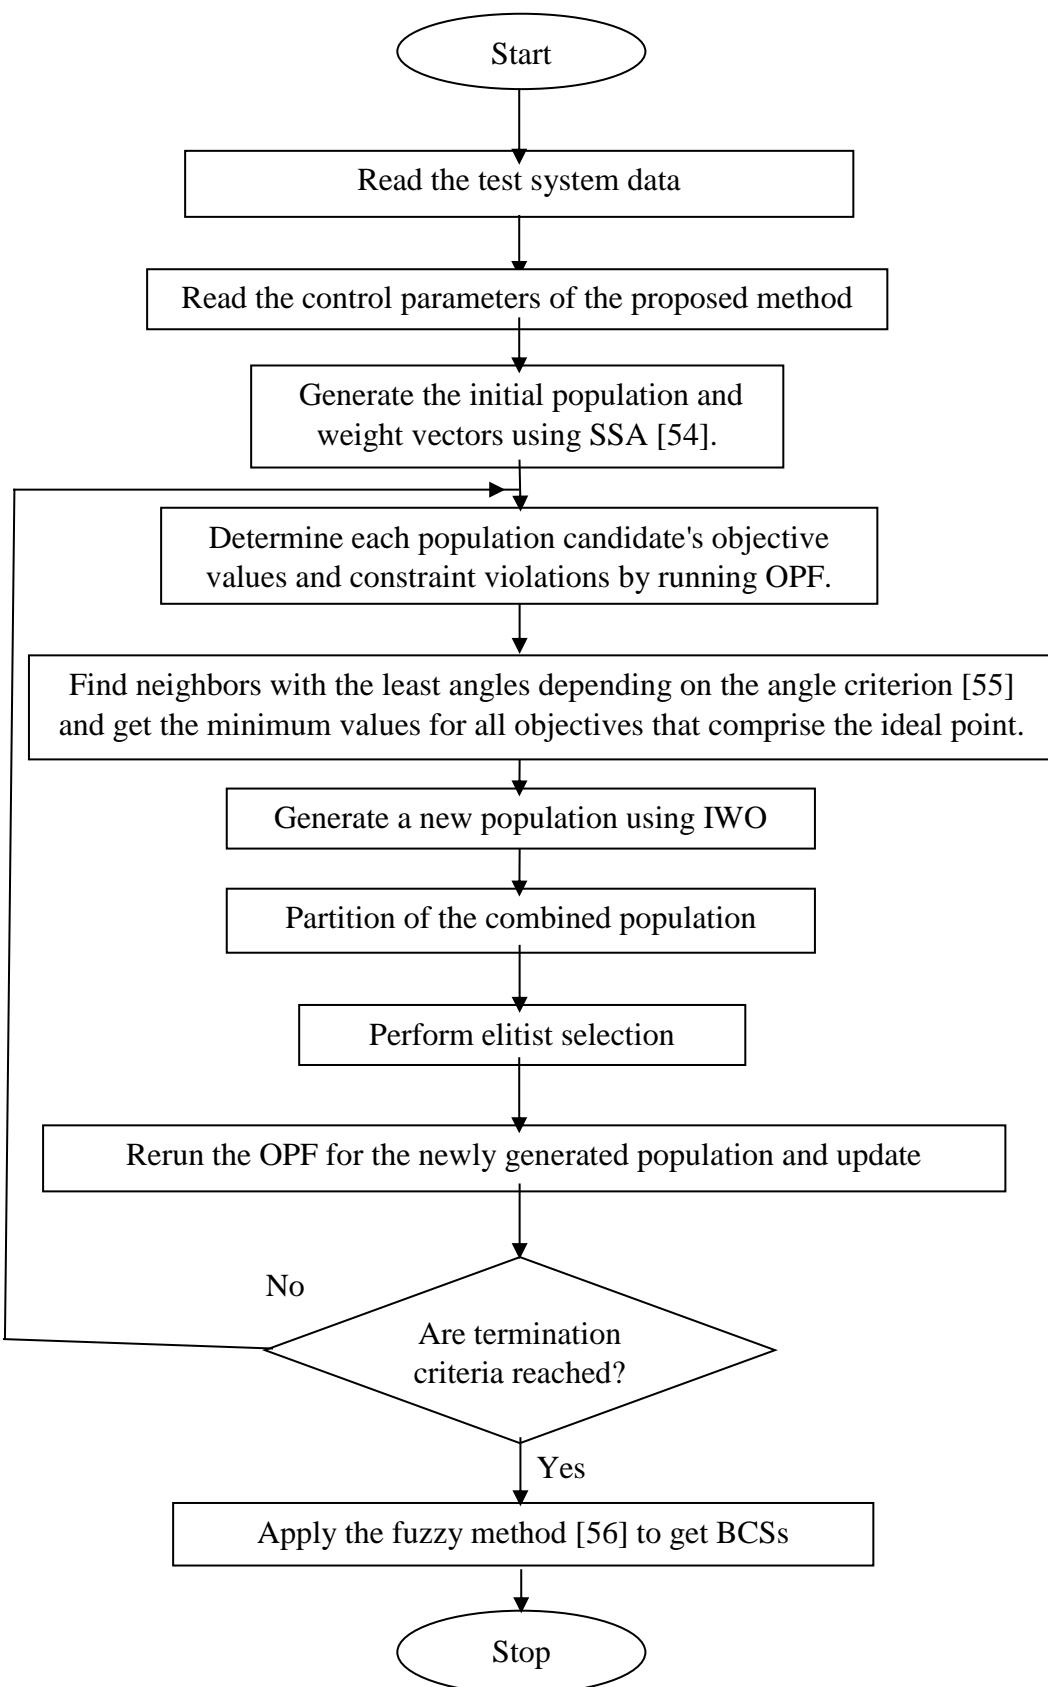

$$g_{mean}^{te} = \frac{\sum\{g^{te}(x^k | \lambda^i, z^*) | x^k \in B(i)\}}{|B(i)|} \quad (6.42)$$

Where  $g^{te}$  be the value of the weed's aggregated scalar function,  $g_{min}^{te}$ ,  $g_{max}^{te}$  and  $g_{mean}^{te}$  are the lowest, highest, and mean values of weeds in the present iteration respectively, and  $Q$  is the regulatory parameter whose value ranges from 0 to 0.5.  $|B(i)|$  is the number of neighbors of  $i^{th}$  sub-problem. Similarly, the same model was applied to the neighbors of  $x^i$  in line 8 of the algorithm.

Let  $x^i = (x_1^i, x_2^i, \dots, x_n^i)^T$  is the  $i^{th}$  parent individual,  $y = (y_1, y_2, \dots, y_n)^T$  are the seeds generated by  $x^i$ ; where each element  $y_j$  is produced as follows:

$$y_j = x_j^i + N(0, std_{iter}^2); j = 1, 2, \dots, n. \quad (6.43)$$

Then the trade-off objective optimal value is selected using the fuzzy method [56].

**Fig.6.1:** Flowchart of the proposed method

## 6.6 Results and Discussions

To analyze the robustness and efficacy of the suggested method, IEEE 57-bus and 118-bus systems were taken into account. The proposed method was implemented in MATLAB R2016a, and simulations were conducted over an i3-Processor having 4 GB RAM. To verify the efficacy of the proposed method, comparisons were made with NSGA-II [57] and MOPSO [58]. In this work, the stochastic nature of WECS, SPVS, and PEV sources was taken into account to study the impact of these sources on the MOOPF problem. To consider uncertainties, Monte-Carlo simulations were used to generate 1000 samples. The control parameters of the proposed method, NSGA-II, and MOPSO are given in Table 6.1. The various cases considered are given in Table 6.2. The description of the test systems was given in Table 6.3. PDF specifications and cost components of various sources are given in Table 6.4.

### 6.6.1 IEEE 57-bus system

The IEEE 57-bus system [59] was investigated to demonstrate the performance of the proposed method for solving the MOOPF problem. The information about the IEEE 57-bus system incorporating WECS, SPVS, and PEV sources used is given in Table 6.3. Notably, the locations of these sources were chosen from [74], by replacing load buses with the respective WECS, SPVS, and PEV sources.

#### a) Case-1: Minimize $J_1$ , and $J_2$ simultaneously

In this case, the proposed method was simulated by considering two objectives  $J_1$  and  $J_2$ . The Pareto-optimal fronts (PFs) observed are depicted in Figure 6.2. The optimal decision variables obtained by the proposed method are presented in Table 6.5. The proposed method obtains a total generation cost of **35780.28\$/h**, and emission of **0.8702ton/h**. NSGA-II [57] gives 35850.00\$/h, 0.9928ton/h and MOPSO [58] gives 35910.00\$/h, 1.0120ton/h respectively as shown in Table 6.6.

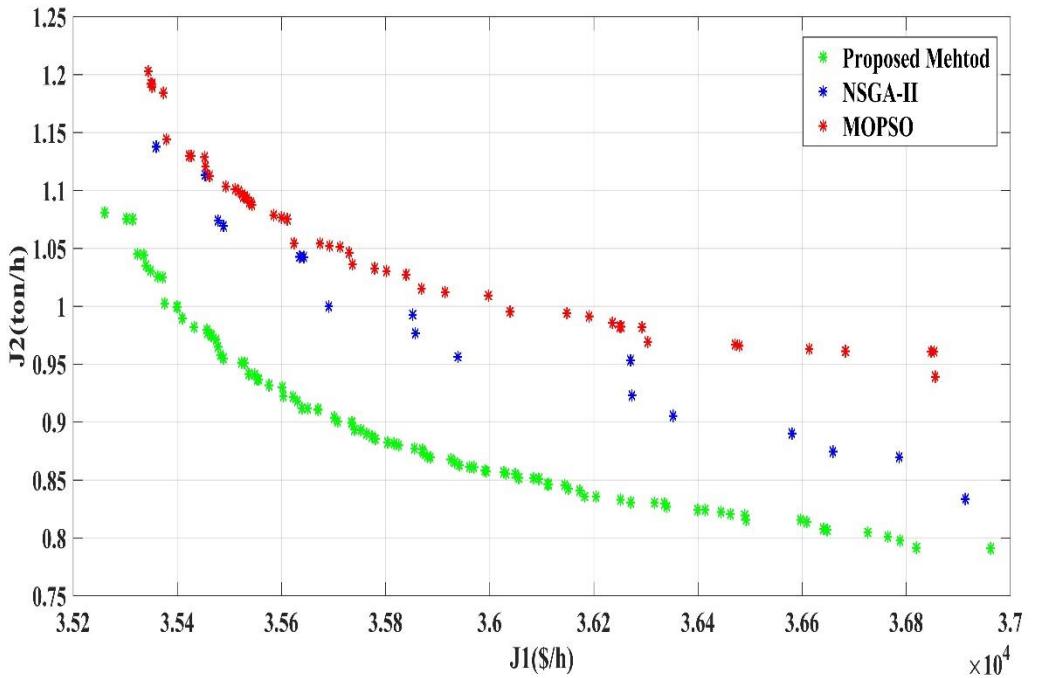

#### b) Case-2: Minimize $J_1$ , $J_2$ , and $J_3$ simultaneously

In this case, the proposed method was simulated by considering three objectives  $J_1$ ,  $J_2$ , and  $J_3$ . The Pareto-optimal fronts (PFs) observed are depicted in Figure 6.2. The optimal decision variables obtained by the proposed method are presented in Table 6.5. The proposed method obtains a total generation cost of **36111.28\$/h**, emission of **0.9568ton/h**, and active power loss of **10.3543MW**. NSGA-II [57] gives 36336.00\$/h, 1.2498ton/h, 11.0813MW and MOPSO [58] gives 36402.69\$/h, 1.0450ton/h, 12.5591MW respectively as shown in Table 6.6.

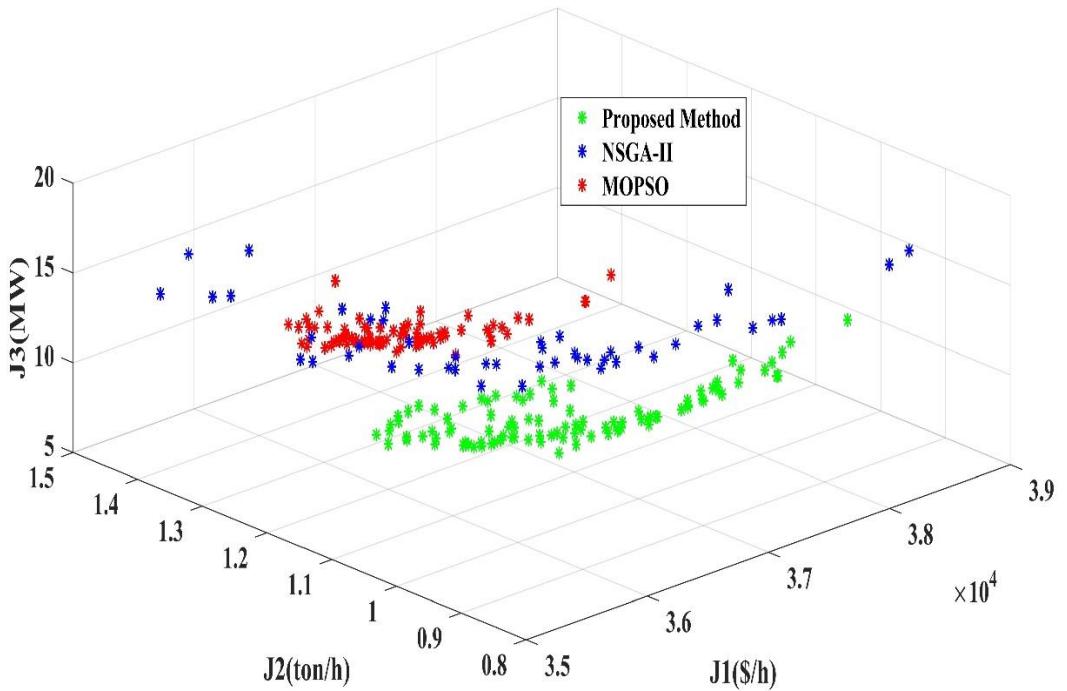

#### c) Case-3: Minimize $J_1$ , $J_2$ , $J_3$ , and $J_4$ simultaneously

In this case, the proposed method was simulated by considering four objectives  $J_1$ ,  $J_2$ ,  $J_3$ , and  $J_4$ . The optimal decision variables obtained by the proposed method are presented in Table 6.5. The proposed method obtains a total generation cost of **36340.27\$/h**, emission of **1.1009ton/h**, active power loss of **10.9504MW**, and voltage magnitude deviation of **0.8519p.u.** NSGA-II

[57] gives 36250.00\$/h, 1.4175ton/h, 12.3871MW, 1.0481p.u. and MOPSO [58] gives 36662.59\$/h, 0.9367ton/h, 14.1833MW, 1.0669p.u. respectively as shown in Table 6.6.

### 6.6.2 IEEE 118-bus system

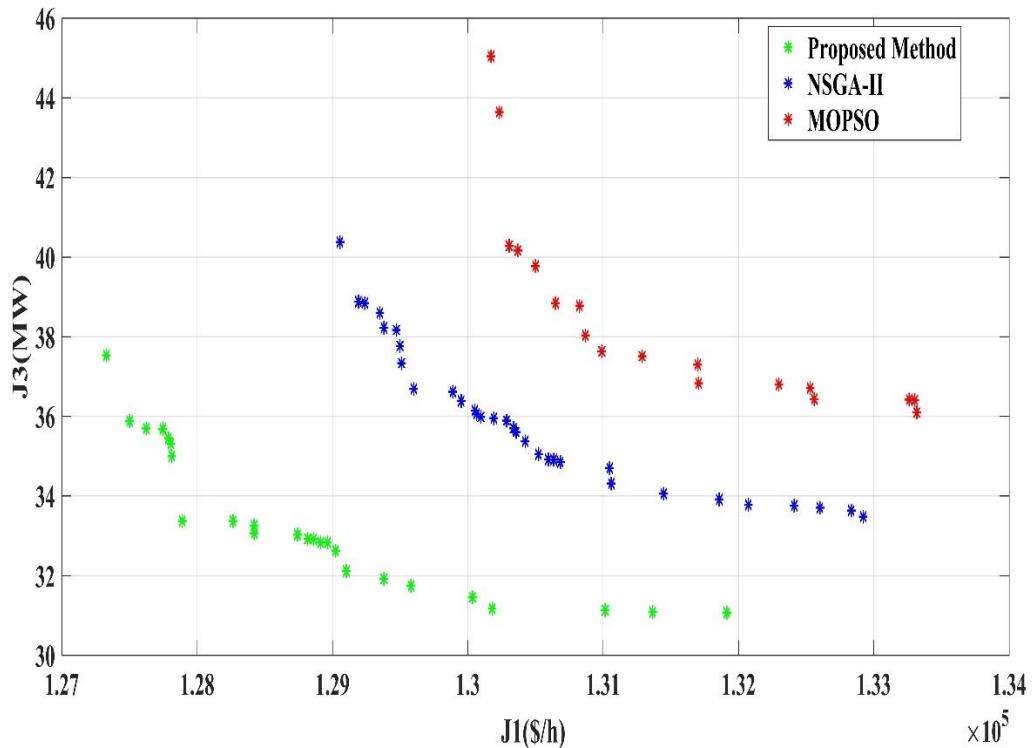

The IEEE 118-bus system [59] was considered to demonstrate the efficacy of the proposed method on a big system. The information about the IEEE 118-bus system incorporating WECS, SPVS, and PEV sources used is given in Table 6.3. Notably, the locations of these sources were chosen from [74], by replacing load buses with the respective WECS, SPVS, and PEV sources.

#### a) Case-4: Minimize $J_1$ , and $J_3$ simultaneously

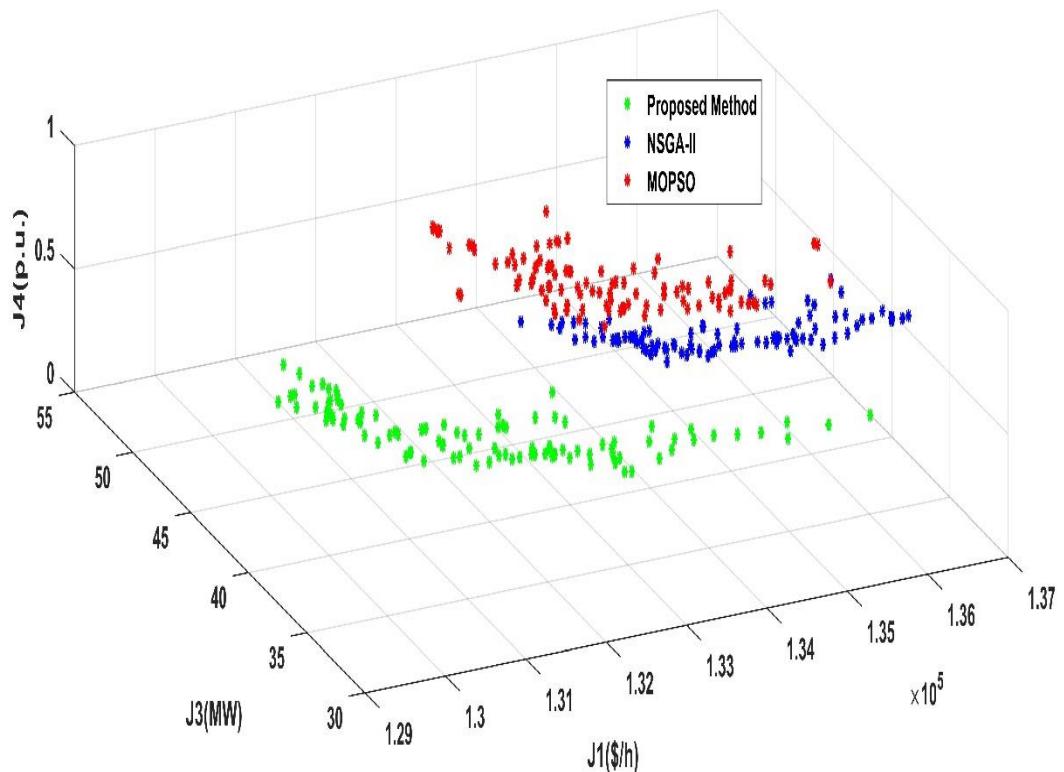

In this case, the proposed method was simulated by considering two objectives  $J_1$ , and  $J_3$ . The Pareto-optimal fronts (PFs) observed are depicted in Figure 6.3. The optimal decision variables obtained by the proposed method are presented in Table 6.7. The proposed method obtains a total generation cost of **127890.61\$/h**, and an active power loss of **33.3705MW**. NSGA-II [57] gives 129582.23\$/h, 37.3464MW and MOPSO [58] gives 130673.5\$/h, 38.0368MW respectively as shown in Table 6.8.

#### b) Case-5: Minimize $J_1$ , $J_3$ , and $J_4$ simultaneously

In this case, the proposed method was simulated by considering three objectives  $J_1$ ,  $J_3$ , and  $J_4$ . The Pareto-optimal fronts (PFs) observed are depicted in Figure 6.3. The optimal decision variables obtained by the proposed method are presented in Table 6.7. The proposed method obtains a total generation cost of **130749.11\$/h**, active power loss of **38.2259MW**, and voltage magnitude deviation of **0.4511p.u.** NSGA-II [57] gives 134395.5\$/h, 40.0724MW, 0.6876p.u. and MOPSO [58] gives 133574.6\$/h, 41.3020MW, 0.9706p.u. respectively as shown in Table 6.8.

## 6.7 Summary

This chapter introduced a solution to the MOOPF problem in a thermal, WECS, SPVS, and PEV integrated power system using hybrid MOEA based on decomposition and IWO methods. It also addressed the constraints of the MOOPF problem with the superiority of the feasible solution (SF) method. In conjunction with the minimization of emission, active power loss, and voltage magnitude deviation, the generation cost of thermal generators and the uncertainty cost of WECS, SPVS, and PEV systems were reduced. The unpredictability of WECS, SPVS, and PEV powers was assessed with Monte Carlo simulations. To illustrate the efficacy of the proposed technique, simulations were done on the IEEE 57-bus and IEEE 118-bus systems, and the results were compared with NSGA-II and MOPSO algorithms. The outcomes indicate that the proposed technique is much more reliable and superior to existing techniques.

# **Chapter 7**

## **Conclusions**

# Chapter 7

## Conclusions

In this thesis, the power system OPF problem was solved using new hybrid MOEAs. The thesis explored the new multi-objective frameworks such as decomposition-based MOEAs and their application to the MOOPF problem. Furthermore, stochastic WECS, SPVS, and PEV systems were integrated into the conventional OPF to study the impact of uncertainty. Since MOOPF is a constrained problem, in this thesis, effective constraint handling methods were proposed for solving the OPF problem. A fuzzy method was used to obtain the best-compromised solution among the solutions obtained. This chapter presents the important findings proposed through the research work and discusses future extensions of the proposed research work.

### 7.1 Summary of Important Findings

The following conclusions were arrived at from the research work carried out and reported in previous chapters of this thesis.

- 1) A new hybrid decomposition and local dominance-based MOEA was proposed for the OPF problem.
  - The MOOPF problem was modeled with four objectives: minimizing total generation cost, emission, active power loss, and voltage magnitude deviation.
  - The hybridization of decomposition and dominance methodologies increased the Pareto front's convergence and diversity of solutions.
  - The MOOPF problem constraints were handled using a static-penalty method, in which a penalty is imposed to the fitness of the infeasible solutions with this all infeasible solutions are discarded and only considers feasible ones, and this would help in achieving the global optimal solution.
  - The results of the proposed method were compared with NSGA-II and MOPSO and demonstrated on IEEE 57-bus and IEEE 118-bus systems.
- 2) A new hybrid decomposition and summation of normalized objectives with improved diversified selection-based MOEA were proposed for solving the OPF problem including the WECS, and SPVS uncertainty.
  - Integrating RESs like WECS and SPVS sources with conventional OPF to consider the impact of the uncertain nature of these sources. The uncertain nature of RESs was modeled using PDFs and their uncertainty cost was calculated using Monte-Carlo simulations.

- A new constraint handling method was adopted so that it enhances the quality of the solution and eliminates the parameter dependence in handling constraints.
- The proposed method was tested on IEEE 57-bus and IEEE 118-bus systems. The findings obtained demonstrate that the proposed strategy is superior to NSGA-II and MOPSO.

3) A novel hybrid decomposition and summation of normalized objectives with improved diversified selection-based MOEA was proposed for OPF problems including WECS, SPVS, and PEV system uncertainty.

- The MOOPF problem was designed with four objectives: minimizing total generation cost, emission, active power loss, and voltage magnitude deviation.
- A new constraint handling method was adopted so that it enhances the quality of the solution and eliminates the parameter dependence in handling constraints.
- The impact of WECS, SPVS generation, as well as PEV uncertainties, was taken into account to validate the proposed method.
- The proposed method was tested on IEEE 57-bus and IEEE 118-bus systems. The findings obtained demonstrate that the proposed strategy is superior to NSGA-II and MOPSO.

4) A new hybrid decomposition and invasive weed optimization (IWO) based MOEA was proposed for OPF including WECS, SPVS, and PEV system uncertainty.

- The MOOPF problem was designed with four objectives: minimizing total generation cost, emission, active power loss, and voltage magnitude deviation.
- A new constraint handling method was adopted so that it enhances the quality of the solution and eliminates the parameter dependence in handling constraints.
- The impact of WECS, SPVS generation, as well as PEV uncertainties, was taken into account to validate the proposed method.
- The proposed method was tested on IEEE 57-bus and IEEE 118-bus systems. The findings obtained demonstrate that the proposed strategy is superior to NSGA-II and MOPSO.

## **7.2 Scope of the Future Work**

The present research can be extended for future research. The probable areas where research can be contemplated are:

- Big data, data analytics techniques, and machine learning methods can be used to model multi-objective framework design to adopt problem-specific and computationally complex problems like the MOOPF problems.
- To evaluate the efficacy of MOEAs for multi-objective optimization problems, other CHM such as epsilon constraint (EC), and stochastic ranking (SR) can be combined.
- To discover the best-compromised solutions, more sophisticated decision-making techniques may be utilized, such as the pseudo-weight method, and  $L_p$  metric.
- Future research will continue to focus on the dynamic optimal power flow (DOPF) problem, which takes into account the ramping rate of generators, variations in load needs across time, the stochastic character of all renewable sources, and all network restrictions.

## Publications

### Journals- SCIE/SCOPUS-Indexed:

- 1) **Ravi Kumar Avvari** and Vinod Kumar D.M. “A New Hybrid Evolutionary Algorithm for Multi-Objective Optimal Power Flow in an Integrated WE, PV, and PEV Power System.” **Electric Power Systems Research**, Elsevier, Vol. 214, 108870, Jan 2023. (**SCIE, IF: 3.818**).
- 2) **Ravi Kumar Avvari** and Vinod Kumar D.M. “Multi-Objective Optimal Power Flow including Wind and Solar Generation Uncertainty Using New Hybrid Evolutionary Algorithm with Efficient Constraint Handling Method.” **International Transactions on Electrical Energy Systems**, Wiley, Vol. 2022, 7091937, Jul 2022. (**SCIE, IF: 2.639**).
- 3) **Ravi Kumar Avvari** and Vinod Kumar D.M. “Multi-Objective Optimal Power Flow with efficient Constraint Handling using Hybrid Decomposition and Local Dominance Method.” **Journal of The Institution of Engineers (India): Series B**, Springer, Vol. 103, No. 5, pp. 1643-1658, Oct 2022. (**Scopus**).
- 4) **Ravi Kumar Avvari** and Vinod Kumar D.M. “A Novel Hybrid Multi-Objective Evolutionary Algorithm for Optimal Power Flow in Wind, PV, and PEV Systems.” **Journal of Operation and Automation in Power Engineering**, Vol. 11, No. 2, pp. 130-143, Aug 2023. (**Scopus**).

## Curriculum-Vitae

Name:	Avvari Ravi Kumar
Date of Birth:	23 November, 1991
Gender:	Male
Contact Number:	+91-7382405100
Email Id:	avvari.ravi@gmail.com

### Academic Qualifications:

Program	Specialization	University	Division	Year of Completion
M.Tech	Electrical Power Systems	JNTUH, Hyderabad	First Class with Distinction	2015
B.Tech.	Electrical and Electronics Engineering	Sri Venkateswara University, Tirupati	First Class with Distinction	2013
