CERTIFICATE

This is to certify that the dissertation work entitled "**MECHANICAL AND TRIBOLOGICAL CHARACTERIZATION OF RED MUD AND TUNGSTEN CARBIDE PARTICLE REINFORCED ALUMINIUM METAL MATRIX HYBRID COMPOSITES**", which is being submitted by **Mrs. Neelima Devi Chinta**(Roll No.701111), is a bonafide work submitted to the Department of Mechanical Engineering, National Institute of Technology, Warangal in partial fulfilment of the requirement for the award of the degree of **Doctor of Philosophy in Mechanical Engineering**.

To the best of our knowledge, the work embodied in this thesis has not been submitted to any other university or institute for the award of any other degree.

Prof. V.Mahesh
Co-Supervisor
Department of Mechanical Engineering
S.R. Engineering College

DECLARATION

This is to certify that the work presented in the thesis entitled. "**MECHANICAL AND TRIBOLOGICAL CHARACTERIZATION OF RED MUD AND TUNGSTEN CARBIDE PARTICLE REINFORCED ALUMINIUM METAL MATRIX HYBRID COMPOSITES**" is a bonafide work done by me under the supervision of Prof.N.Selvaraj and Prof. V.Mahesh. It was not submitted elsewhere for the award of any degree. I declare that this written submission represents my ideas in my own words and where others' ideas or words have been included, I have adequately cited and referenced the original sources. I also declare that I have adhered to all principles of academic honesty and integrity and have not misrepresented or fabricated or falsified any idea / data / fact / source in my submission. I understand that any violation of the above will be a cause for disciplinary action by the Institute and can also evoke penal action from the sources which have thus not been properly cited or from whom proper permission has not been taken when needed.

ABSTRACT

Aluminium metal matrix hybrid composites have evoked a keen interest in recent times for potential applications in aerospace and structural applications owing to their superior strength-to-weight ratio and high temperature resistance. Using high performance materials, it is possible for the modern aircraft to rotate larger degree while retaining its strength in both the airframe and propulsion systems. To obtain continual performance, designers are constantly searching for lighter and stronger materials.

The attractiveness of aluminum is that it is a relatively low cost, light weight metal that can be heat treated to fairly high strength levels and it is one of the most easily fabricated high performance materials. Metal matrix hybrid composites have the future of fulfilling these requirements. The present work is focussed on the characterisation of the mechanical and wear behaviour of red mud and tungsten carbide particle reinforced aluminium through conventional sintering.

The objective of this research work is aimed at finding out utilization of industrial byproducts such as red mud for value added applications and also helps to solve the environmental problems. In the current work, aluminium is mixed with red mud at micro as well as nano level and tungsten carbide to form metal matrix hybrid composites, synthesized by powder metallurgy, which exhibit superior mechanical and tribological properties and applications.

An environmental hazardous waste material, red mud is obtained from bayer's process during the processing of alumina. Red mud received from NALCO (National Aluminium Corporation) has been subjected to sieve analysis for micron level of 100 μm , 150 μm and 200 μm and milled to nano level of 42 nm using high energy ball mill. Hardness and compression strength properties are improved for nano level red mud with pure aluminium test specimen at 42 nm size and 6% weight fraction of red mud. As compared to micro level, nano level has achieved the highest wear resistance due to the interfacial area between the aluminium matrix material and reinforced red mud material.

The mechanical property such as hardness is found at normal condition and heat treatment conditions, for which mathematical modeling is done by regression analysis. Further compression test and validation of compression test is performed with Deform -2D Software. An increase in hardness and compression strength is observed with increase in the amount of percentage weight fraction of red mud. Hardness values variation depicts the information that nano red mud specimens have more hardness when compared with micro nature specimens.

Micro structural observation such as Scanning Electron Microscope (SEM) analysis and Energy Dispersive X-Ray Spectroscopy (EDX) are performed. The work also investigates on tribological characterization such as wear behavior of pure aluminium with red mud at normal and heat treatment conditions with varying 2%, 4% and 6% weight fractions of red mud, particle size of 100 μm and 42 nm and 200 rpm, 400 rpm and 600 rpm speed of pin-on-disc wear testing machine at 10N, 20N and 30N load.

The mathematical modeling is done by regression analysis for prediction of wear behaviour at normal and heat treatment conditions. The predicted equations at normal and heat treatment conditions are significant in nature with near unity R square values. The predicted mathematical modeling results of wear rate using regression analysis and experimental values are within the limits of 1-4% error difference of pure aluminium-red mud metal matrix composites and pure aluminium-red mud-tungsten carbide hybrid metal matrix composites.

NOMENCLATURE/ABBREVIATIONS

Al - Aluminium

RM - Red mud

WC - Tungsten Carbide

P/M – Powder Metallurgy

μm - micro meter

nm - nano meter

VHN - Vickers Hardness Number

Φ - Diameter

% - Percentage

MPa - Mega Pascals

ρ – Density, kg/m^3

m_1 - Initial mass, gm

m_2 - Final mass, gm

Δm - Initial mass – Final mass, gm

V_s - Sliding velocity, m/sec

t – Time, sec

F_f - Average frictional force, kgf

F_n - Applied load, kgf

μ - Co-efficient of friction = F_f / F_n

R.D - Rolling / Sliding distance (L), m

W_r - Wear rate = $\Delta m/L$, N/m

W_v - Volumetric Wear rate = $\Delta m / \rho t$, m^3/sec

W_s - Specific Wear rate = $W_v / (V_s F_n)$, $m^3/N\cdot m$

RPM - Revolutions Per Minute

μ - Co-efficient of friction

XRD - X - Ray Diffraction

SEM - Scanning Electron Microscope

EDX – Energy Dispersive X-Ray Spectroscopy

0C – Degree Centigrade

N/m – Newton per metre

Kgf – Kilogram force

CHAPTER 1

INTRODUCTION

The beginning of the history with stone age followed by bronze, iron, aluminium and its alloys are significant for the growth of science and technology. The capabilities of higher strength, light weight, and cost effective composites are pioneered in the world of advanced materials [1-3]. Nowadays there is a tremendous usage of composites with good structural properties, better thermal, tribological, electrical and environmental applications. The present chapter is describing composites, types of composites and their manufacturing methods.

1.1 ENGINEERING MATERIALS AND THEIR APPLICATIONS

Many of the modern technologies require new engineering materials with exceptional combinations of properties that cannot be met by the conventional metal alloys and polymeric materials. This is especially true for engineering materials that are needed for automobile, aerospace, underwater and structural applications. Automobile and aircraft engineers are tremendously searching for new engineering materials that have low densities, strong, abrasion, corrosion and impact resistant.

In engineering, an accomplishment design depends on upon the selection of materials having the most desirable properties for a given application. While at the same time, the cost is also an important consideration for the selection of materials [5]. Nowadays, the scientists, researchers and engineers have ingeniously mixed various metals, ceramics and polymers to develop a new generation of extraordinary materials. Most of the engineering materials have been created in the form of composites to improve the wear behaviour and mechanical characteristics such as hardness, compression strength, stiffness, toughness and high-temperature resistance [5]. The new engineering materials are used in automotive industry, aerospace, sporting goods and construction purpose etc., [6-8].

1.2 ALUMINIUM COMPOSITES

A composite material consists of two or more distinct physical and/or chemical in nature constituents with separating interface / interphase between them. The constituents of composite materials are named as matrix and reinforcement materials. Composite materials are broadly classified into Metal Matrix Composites (MMC), Polymer Matrix Composites (PMC) and Ceramic Matrix Composites (CMC) [81-84]. The polymer matrix composites have poor high-temperature capabilities, low strength, and stiffness. The ceramic matrix composites have very low toughness and difficult to machine [9].

1.2.1 Salient features of Metal Matrix Composites (MMC)

The metal matrix composites (MMC) are having good strength, ductility, high toughness, magnetic properties, electrical and thermal conductive [85-86]. According to the type of reinforcement, particle, laminar, flake, fiber and filler varieties are reinforced matrix composites [78]. The various types of composites based on reinforcement are shown in Figure 1.1.

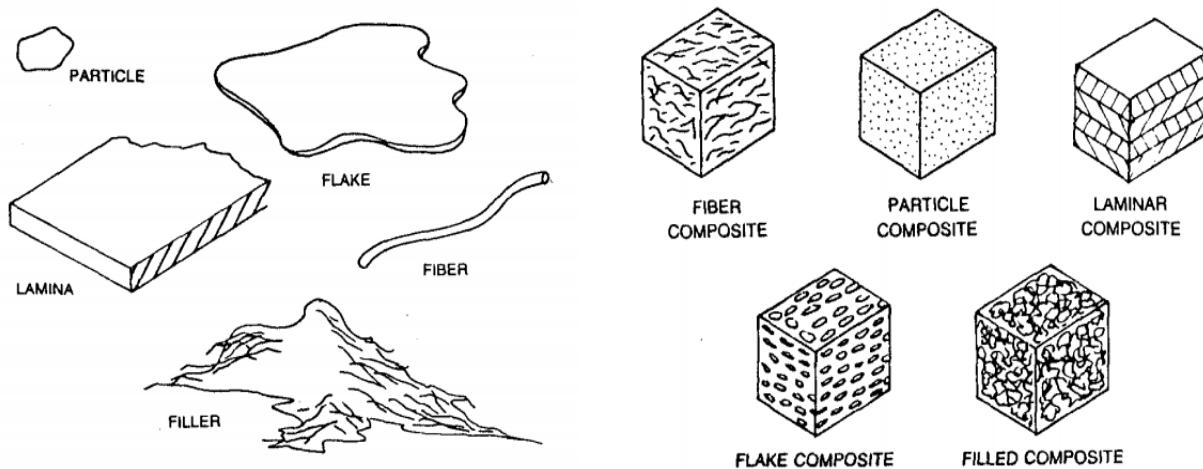

Figure 1.1: Various types of composites based on reinforcement

Aluminium is a soft, light, gray metal that resists corrosion when pure, regardless of its chemical activity because of a thin surface layer of oxide [90]. Aluminium has a wide range of applications in the aerospace and automotive industries due to better strength-to-weight ratio. The reduction in weight saves the fuel requirements and emissions which in turn affects the cost problems and environmental advantages [18 and 88].

Aluminium metal matrix composites have the more impact and potential to be utilized in various applications of engineering fields such as aerospace, automobile, naval, mechanical, structural and defence organizations [11, 13-14, 21-22]. The various applications of aluminium composites are as shown in Figure 1.2.

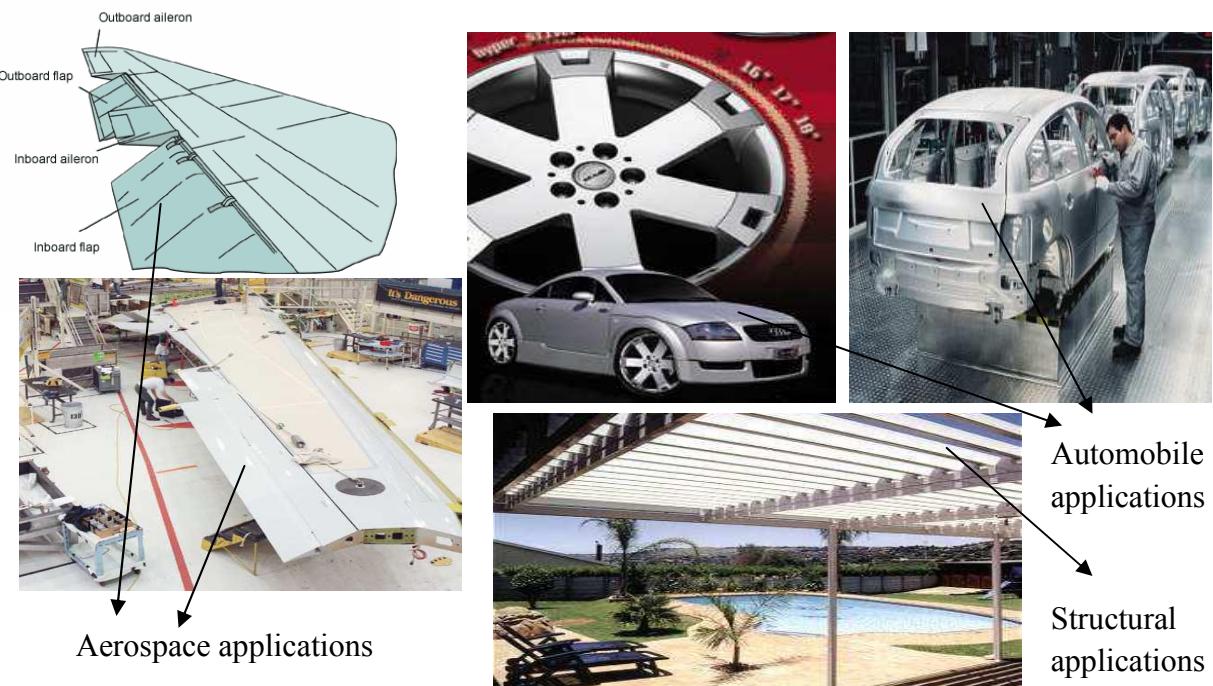

Figure 1.2: Various applications of aluminium composites

The main limitation of aluminium composites is not satisfying the combination of desired needs for advanced engineering applications such as manufacturing of Boeing 767, Airbus A 380 and race cars etc.

1.3 ALUMINIUM HYBRID COMPOSITES

Aluminium hybrid composites are finding increased demand and usage in new aircraft designs due to their higher strength capabilities. Aluminium metal matrix hybrid composites have considerable importance since their mechanical and tribological properties are superior over non-reinforced alloys [4-6]. Aluminium-red mud-tungsten carbide hybrid composites will become alternative materials for different engineering applications with their excellent qualities like light weight, environment friendliness, quality, performance with superior mechanical properties, wear characteristics and low cost [10, 19-20]. Therefore, the innate ability of aluminium hybrid composites with a wide variety of applications are lying in various research activities all over the world [58, 62, 70].

The potential demands are met with a number of performance capabilities such as improved mechanical characteristics and better tribological behaviour etc., using hybrid composites. The applications of aluminium hybrid composites are shown in Figure 1.3.

Figure 1.3: Applications of aluminium hybrid composites

1.4 MANUFACTURING METHODS

The suitability of various manufacturing methods for composite materials depends on engineering applications, synthesis of the material, characteristics of the matrix material, reinforcement material, and heat treatment conditions.

1.4.1 Solid state manufacturing methods

There are many ways to manufacture metal matrix composites by solid state techniques.

1.4.1.1 Diffusion Bonding

Diffusion bonding is defined as common solid state welding method used to join similar or dissimilar metals. There are many variants of the basic diffusion bonding process; however, all of them involve a step of simultaneous application of pressure and high temperature. Interdiffusion of atoms from clean metal surfaces in contact at an elevated temperature leads to welding. Matrix alloy foil and fiber arrays, composite wire, or monolayer laminae are stacked in a predetermined order. Figure 1.4 shows diffusion bonding technique, also called the foil-fiber-foil process.

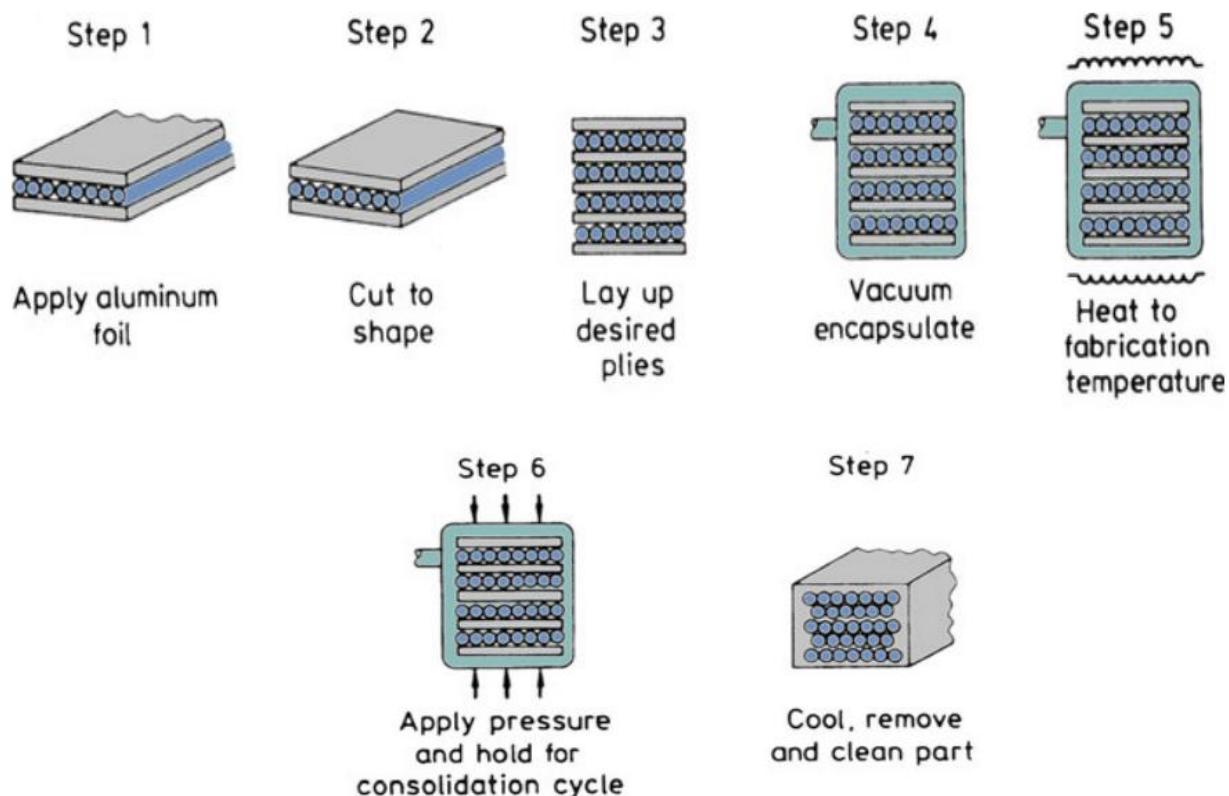

Figure 1.4: Diffusion bonding technique [Courtesy of J. Baughman]

1.4.1.2 Powder Metallurgy Route

The processing of powder metallurgy can be divided into four stages. Preparation of the powder, mixing or blending of powders in desired proportions, compacting the powders into desired shapes in suitable dies at specified pressures and sintering the compacted components in furnaces provided with controlled atmospheres. For the preparation of powders, mechanical pulverization, atomization, chemical reduction process and electrolytic process are used. Sintering involves the heat treatment of powder compacts at elevated temperatures, in the temperature range where diffusion mass transport is appreciable [10-11, 72]. The different stages involved in the sintering process are as shown in Figure 1.5.

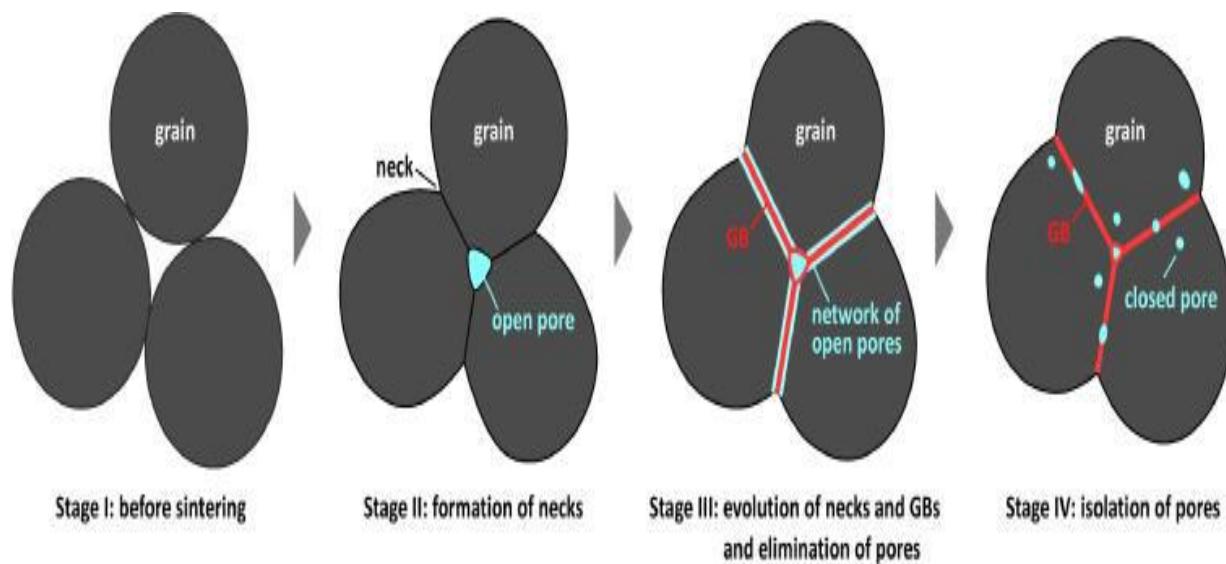

Figure 1.5: Different stages involved in sintering process

1.4.2 Liquid state manufacturing methods

There are different methods to manufacture metal matrix composites by liquid state techniques.

1.4.2.1 Liquid Infiltration method

Liquid-phase infiltration faces difficulties mainly with ceramic reinforced material in wet condition to prepare MMCs. Before infiltration, fiber coatings are applied which increases the wettability and control reactions.

1.4.2.2 Squeeze Casting

The squeeze casting process is shown in Figure 1.6. In this process, application of pressure can be done upto solidification. The molten metal is imposing through tiny pores of the fibrous material. Better wettability between the reinforced material and matrix can be obtained in squeeze casting [44].

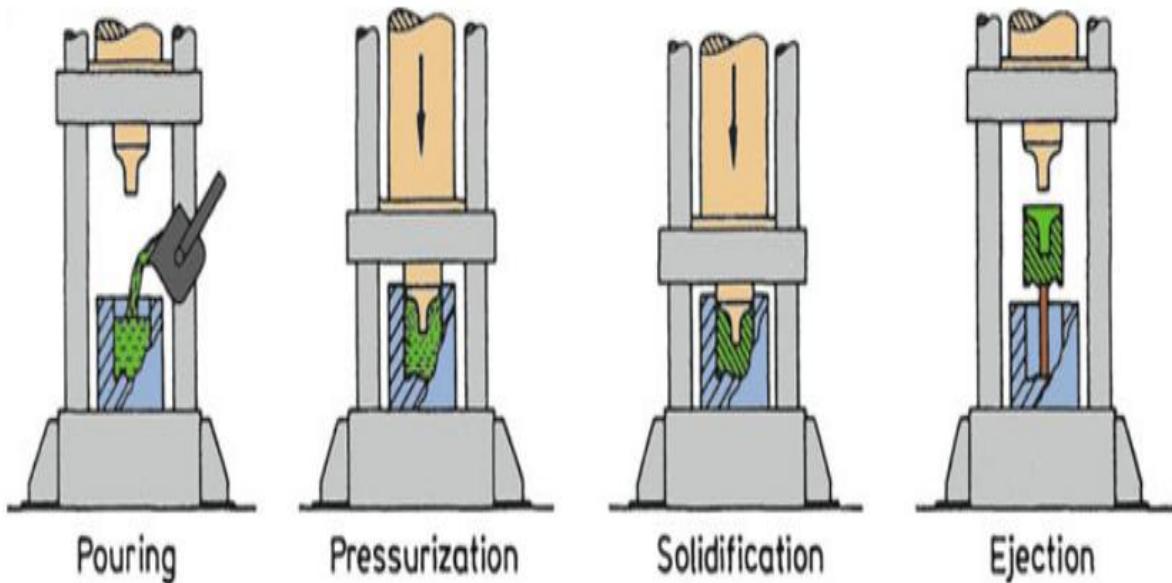

Figure 1.6: Squeeze casting process

[Courtesy of G. Eggeler]

1.4.2.3 Spray forming Technique

The Spray forming technique is very fast and totally computer-controlled method. In this technique, spray gun is utilized to atomize the molten aluminum alloy matrix. Ceramic particulates like silicon carbide are injected into this stream. Figure 1.7 shows a schematic of spray forming process.

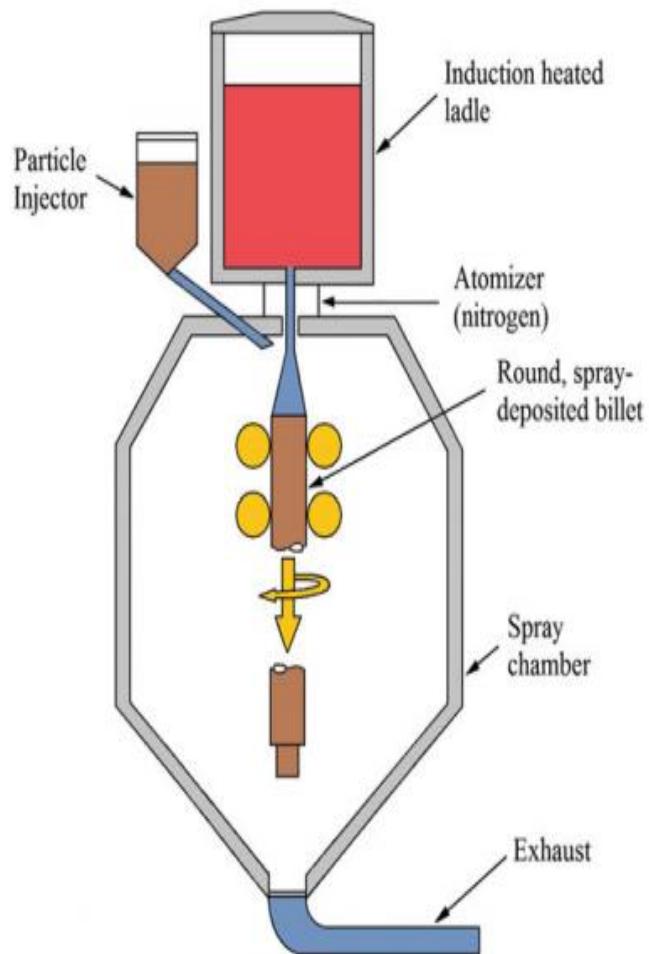

Figure 1.7: Spray forming process

[Courtesy of Krishan. K.Chawla]

1.4.2.4 Compocasting

Compocasting is one of the most economical methods of fabricating a composite with discontinuous fibers. It can be performed at temperatures lower than those conventionally employed in foundry practice during pouring, resulting in reduced thermochemical degradation of the reinforced surface. When a liquid metal is vigorously stirred during solidification, it forms slurry of fine, spheroidal solids floating in the liquid. Stirring at high speeds creates a high shear rate, which tends to reduce the viscosity of the slurry even at solid fractions as high as 50 to 60% volume. The process of casting such slurry is called rheocasting [56]. The slurry can be blended with short fibers or whiskers, particulates prior to casting. The new developed method of rheocasting is to produce metal matrix composite parts known as Compocasting. Compocasting owns a homogeneous distribution of reinforced material in the matrix. Continuous mixing of the slurry creates good contact between reinforcement material and matrix. Better bonding is obtained by decreasing the slurry viscosity as well as improving the mixing time. [9].

1.4.2.5 Stir casting

Stir-casting technique is used for producing metal matrix composites. In this technique, the reinforced particulates and matrix material are mixed in crucible and then it is poured into desired mould shape before the complete solidification [62 and 65-66]. In this process, wettability between reinforced material and matrix material is difficult without proper stirring. In the Figure 1.8 a) stir casting equipment and Figure 1.8 b) the crucible inside the stir casting furnace are shown.

Figure 1.8: a) Stir casting equipment

b) Crucible inside the stir casting furnace

In this present work, powder metallurgy route has been adopted for preparing the hybrid metal matrix composites out of all manufacturing methods. Powder metallurgy process has efficient material utilization. Powder metallurgy is used for better material characteristics. Their improved material characteristics make them potentially suitable for several applications in aerospace like airframe structures, wings, fuselage, light structures, engine components and other structural applications. Light weight machine components, drive belt pulleys, hubs, caps and connection collars are manufactured through powder metallurgy route in marine industry. The automobile components such as shock absorber, oil transmission gears, piston, cam shaft, pulleys, rod guides, anti-lock breaking system and push rods etc., are prepared through powder metallurgy. Powder metallurgy process has the capability of manufacturing complex shapes and parts. It is suitable for medium to high volume range component production. Furthermore, parts that require very close dimensional tolerances (e.g., gears and bushings) may be economically produced using powder metallurgy technique.

1.5 ORGANIZATION OF THE THESIS

The entire thesis has been divided into seven chapters and its details are given below.

1. Chapter - 1 presents the comprehensive overview of aluminium composites, aluminium hybrid composites, and manufacturing methods. The significance of engineering materials and their applications are discussed.
2. Chapter – 2 provides a review of literature relevant to the current investigation. The main objective of the critical review of the literature was to carefully examine any research works done previously related to the present work and identified the gaps from literature. It reports the motivation, objectives, aim and overall research plan of the thesis.
3. Chapter - 3 gives the selection of materials, experimental details on high energy ball milling, X-Ray Diffraction (XRD) analysis for nano red mud, the experimental setup for conventional sintering through powder metallurgy for sample preparation.
4. Chapter - 4 presents mechanical characterization of pure aluminium with red mud and pure aluminium with red mud and tungsten carbide such as hardness at normal and heat treatment conditions, mathematical modeling using regression analysis for hardness values at normal and heat treatment conditions, compression test and validation of compression test results with Deform -2D software and microstructural observations such as SEM and EDX used in the current work.
5. Chapter - 5 provides a tribological characterization of pure aluminium with red mud at normal and heat treatment conditions and mathematical modeling using regression analysis for various testing conditions.
6. Chapter - 6 presents results and discussions of the investigations in which the experimental results of the tribological characterization of pure aluminium with red mud and tungsten carbide at normal and heat treatment conditions are analyzed. The mathematical modeling using regression analysis for various testing conditions are discussed.

7. Chapter - 7 contains the conclusions drawn from the current research work, limitation of work and the scope for future research work.

1.6 SUMMARY

The present chapter gives the introduction to the engineering materials and their applications are discussed. The importance of aluminium composites and aluminium hybrid composites are provided in this chapter. The present chapter also provides the various manufacturing methods and organization of the thesis.

CHAPTER-2

LITERATURE REVIEW

2.1 INTRODUCTION

The review of the literature was carried out on various engineering materials and their applications, metal matrix composites, aluminium composites and aluminium hybrid metal matrix composites. Many researchers have investigated on desirable properties of alloys, composites, metal matrix composites and hybrid composites. Aluminium composites have become more considerable, because of light weight, good strength, better toughness and resistance to wear and corrosion. Recent advancements in material characterization with composite materials were improved using metal matrix composites and hybrid composites.

2.2 ENGINEERING MATERIALS AND THEIR APPLICATIONS

The role of nano-size reinforcement and milling on the synthesis of nano-crystalline aluminium alloy composites by mechanical alloying and their applications were studied. A wide variety of reinforcement particulates such as Al_2O_3 , SiC , B_4C , Si_3N_4 , TiC , TiO_2 , TiB_2 and graphite have been reinforced into aluminium composites. High-energy wet ball milling was successfully employed to synthesize nano crystalline Al 6063 alloy powders reinforced with 1.3 vol.% Al_2O_3 , 1.3 vol.% Y_2O_3 and 0.65 vol.% Al_2O_3 /0.65 vol.% Y_2O_3 at nano-size level [1].

The various innovative methodologies for the utilisation of wastes from metallurgical and allied industries were investigated. The main limitations of stir cast Al-SiC MMC are improper distribution of SiC reinforcement in matrix and less wettability of SiC reinforcement particle with molten Al. Literature survey indicate that various properties of stir cast Al-SiC MMC depends upon fabrication method, volume fraction, shape, size of particles and distribution and properties of constituents [32, 74, 89]. The utilisation of red mud in different industrial applications and structural investigation relating to the cement activity of bauxite residue which is also known as red mud was studied.

The aluminum alloy (A356.1) matrix composites reinforced with 1.5, 2.5 and 5 vol% nano-particle MgO were fabricated via stir casting method. Optimum amount of reinforcement and

casting temperature were determined by evaluating the density, microstructure and mechanical properties of composites [75]. The annotated equilibrium diagrams of some aluminium alloy systems were reported. Yong Liu et.al, red mud derived from a combined Bayer Process and bauxite calcination method was characterized. The results show that pH of the red mud decreased with increasing duration of storage time. Na dominated among the soluble cations, but the concentration of soluble Na decreased with increasing duration of storage time as a result of leaching [76].

The aluminium alloys through liquid phase sintering were studied and impact of lubricants and aids for sintering were also described [55]. Sintering under pure nitrogen resulted in higher sintered densities as compared with vacuum sintering for this grade of Al alloy. Tensile properties of the degassed and vacuum sintered (and T6 tempered) prealloyed powder compacts were higher than those of the equivalent alloy prepared by elemental mixing and comparable with those of the commercial (wrought) 6061 Al alloys.

The reasonable utilisation of red mud in the cement industry was carried out [79]. It was found that the cement manufactured by red mud having capabilities of reduction in energy consumption and increases the strength of cement which resist from sulphate problem [80]. The development and growth of aluminum P/M as a viable component of the industry is chronicled. This historical profile identifies primary drivers and early pioneers of the technology. Some key advances in monolithic alloy powders and composite powders are reviewed in relation to the fabrication of parts by pressing and sintering.

The usage of red mud for different applications such as the removal of harmful pollutants from water was studied [12]. The development and growth of aluminum P/M as a viable component of the industry is chronicled. This historical profile identifies primary drivers and early pioneers of the technology. Some key advances in monolithic alloy powders and composite powders are reviewed in relation to the fabrication of parts by pressing and sintering [15-17]. The corrosion resistance of various metal matrix composites with aluminium and its automotive applications were investigated.

Red mud (an aluminium industry waste) has received wide attention as an effective adsorbent for water pollution control, showing significant adsorption potential for the removal of various aquatic pollutants. Red mud has been found to be efficient for the removal of various aquatic pollutants, especially arsenic and phosphate. However, there is still a need to investigate the practical utility of these adsorbents on a commercial scale [11-12].

The utilisation of a treated bauxite waste i.e. red mud for environmental sustainability and cement industry applications were reported [51, 60]. The average automobile currently produced in North America contains about 90 kg of aluminum. That figure is expected to grow, driven by environmental needs, the Partnership for a New Generation of Vehicles, safety mandates, consumer preferences, and an increasingly global marketplace. This paper examines those issues, along with current automotive applications for aluminum, the technology being developed to meet future demand, and the forces driving changes in technology [63].

2.3 ALUMINIUM COMPOSITES

The various processing and different properties of discontinuously reinforced aluminium composites were analysed in addition to magnesium metal matrix composites [65]. The effect of fibre reinforcement of aluminium, magnesium and Mg-9Al-1Zn on the wear properties has been investigated [92]. Dry sliding, two- and three-body abrasion and solid particle erosion testing were performed [64, 87]. The results show that the tribological behaviour of metal matrix composites (MMCs) depends very much on the type of MMC and the type of contact situation, *i.e.* tribosystem. In erosion, aluminium and magnesium displayed decreasing wear resistance with higher fibre content whereas the magnesium alloy was hardly affected. The relations between wear rate, wear mechanisms and matrix parameters are discussed [61, 97-103].

Discontinuously-reinforced aluminum (DRA) SiC whisker or particle-reinforced Al-alloy matrix composites produced by P/M methods have progressed toward commercial applications, supported by growing data bases and large-scale production facilities. Attention is presently given to the elastic modulus, plastic, ductile, and toughness characteristics of representative DRA formulations, as well as to the DRAs commercially available in the forms of sheets, extrusions, and optical and instrument grade structures able to supplant beryllium [3].

The high strength and highly-uniform composites produced by compocasting and cold rolling processes were investigated. Silicon carbide reinforced aluminum alloy composite materials produced by casting methods are increasingly used in many engineering fields. Composites fabricated by compocasting method were rolled at five different reductions of 30, 60, 75, 85 and 95%. The rolled specimens exhibited reduced porosity as well as a more uniform particle distribution when compared with the as-cast samples. Microscopic investigations of the composites after 95% reduction showed an excellent uniform distribution of silicon carbide particles in the matrix. During cold rolling process it was observed that the tensile strength and ductility of the samples increased by increasing the reduction content [7].

Many researchers have studied the importance of metal matrix composites for aerospace propulsion systems, the usage of aluminium composites in automotive applications, the wear behaviour of aluminium and various mechanical properties of liquid-phase sintered seeded silicon carbide. The effect of seeding on the microstructure of these liquid-phase sintered materials was investigated. So the adding of seeds did not seem to control the matrix microstructure. The image analysis of microstructures allowed to show that the growth of equiaxed grains was continuous, whereas that of elongated grains occurred in two steps. The influence of microstructure on mechanical properties was also examined. The hardness of materials was inversely proportional to the square root of mean grain diameter and their fracture toughness was proportional to this square root. Such results suggested that the mechanical properties could be controlled by the microstructure [8-9].

The red mud as pulverised fuel and utilisation of iron ore for developing ceramic tiles were investigated. Environmental compatibility of a treated red mud was studied in order to evaluate its

possible recycling in environmental compartments [41]. Moreover, in order to better evaluate the environmental compatibility, three different types of eco-toxicological tests were applied (Microtox™ test, ASTM microalgae toxicity test and sea urchin embryo toxicity test). These chemical and eco-toxicological tests gave encouraging results. The possibility to use this material for treating contaminated waters and soils was evaluated, again with particular attention to the Italian regulatory system, through experiments on the treated red mud metal trapping ability and on the subsequent release of trapped metals, at low pH conditions. The treated red mud showed a general high metal trapping capacity and the release at low pH was generally low [14, 15, 49].

The processing of metal matrix composites using powder metallurgy and strengthening mechanisms were described. The processing methods utilized to manufacture particulate reinforced MMCs can be grouped depending on the temperature of the metallic matrix during processing. Accordingly, the processes can be classified into three categories: (a) liquid phase processes, (b) solid state processes, and (c) two phase (solid-liquid) processes. Regarding physical properties, strengthening in metal matrix composites has been related to dislocations of a very high density in the matrix originating from differential thermal contraction, geometrical constraints and plastic deformation during processing [16-19].

A new development in managing these tailings by converting them into value added products such as ceramic floor and wall tiles for building application. These tiles have high strength and hardness compared to conventional tiles and confirms to most of the EN standards. Energy economy and lower production costs are some other benefits [21, 59]. The wear behaviour of aluminium alloys and preparation of metal matrix composites through the sintering process and Al–Mg–Cu-based composites were studied [21, 24-26, 31, 77].

$\text{Al}_2\text{O}_3/\text{SiC}$ ceramic preforms are processed and liquid aluminium infiltrations were discussed [52]. The Al 356/SiC composites have fabricated and investigated by casting technique for moderate mechanical properties. Heavy-duty operation, especially under tribological conditions, frequently in corrosive environment, requires knowledge on their corrosion resistance. This paper presents the initial results of the research on susceptibility of aluminium alloy matrix composite material reinforced by SiC particles to corrosion. The purpose of the research was to

determine the influence of reinforcing phases, their type and shape on corrosion behaviour in a typical corrosion environment, with low NaCl concentration, in relation to the matrix alloy [53].

The challenges of current and future demands of metal matrix composites and its applications were reported for helping automotive and aerospace engineers. Metal-matrix composites (MMCs) offer a number of potential benefits to the aerospace industry, and these have led to important applications on systems such as the Space Shuttle Orbiter, the Hubble Space Telescope, and communications satellites. However, even after decades of development, MMCs have not seen widespread use. Several technical and non-technical challenges remain to their successful insertion into a variety of space applications. This article attempts to provide an overview of these challenges and potential pathways to resolving them [33, 68, 71].

Aluminium-based metal-matrix composites (MMCs) containing hard particles offer superior operating performance and resistance to wear [57-58]. The Microstructure and different material properties for aluminium metal matrix composites with various conditions were described [65-68]. The synthesis of metal matrix composites in particulate form and wear properties for different metal matrix composites were described. The improvement of the wear properties was substantial, decreasing the wear rate in two orders of magnitude, result that is independent of volume fraction and nature of the reinforcement [57, 64]. The metal matrix composites were developed using red mud which is an industrial waste through stir casting process at micron level only was studied [17, 50]. They found that improved hardness and wear resistance at micron level only done through stir casting.

The processing of metal matrix composites using powder metallurgy was discussed in a comprehensive manner [24, 34-37]. The wear studies of aluminium alloys under dry sliding conditions are described. The sliding wear response of several wrought aluminium alloys (2124, 3004, 5056 and 6092) against a high purity alumina (99.9%) counterpart was investigated, at a fixed sliding speed of 1 m/s and a load range of 23–140 N. The counterpart was chosen so as to minimise the chemically driven aspects of adhesive wear. Severe wear was observed at all loads, with specific wear rates ranging from 0.37×10^{-4} to 2.37×10^{-4} mm³/N m. In all cases a

mechanically mixed layer (MML) was formed, principally from severely work hardened aluminium alloy, but also including fine alumina particles [26-27, 96].

The important factors and parameters were developed to produce metal matrix composites for aerospace challenges [38]. The various advanced applications of aluminium composites were discussed by many researchers. The results of experimental investigation on the characterization and analysis of mechanical properties of composites formed. Three aluminum metal matrix composites reinforced with 10 wt% of B₄C, SiC and Al₂O₃ particles were processed. The stir casting method followed by hot rolling was used for fabrications of aluminium 7075 metal matrix composites, being one of the cost effective industrial methods. [57-58, 70].

2.4 ALUMINIUM HYBRID COMPOSITES

The trends in red mud utilisation in which red mud is mixed with fly ash, lime and water in a ratio of 2:1:0.5:2.43, and then pumped the mixture into the mine to prevent ground subsidence during bauxite mining [94]. The rheological behaviour on hardened state behaviour of cement mortars with the addition of red mud are studied. The cementitious behavior of red mud derived from Bauxite-Calcination method was investigated in this research. Red mud were calcinated in the interval 400–900⁰C to enhance their pozzolanic activity and then characterized in depth through XRD technique with the aim to correlate phase transitions and structural features with the cementitious activity. The cementitious activity of calcinated red mud was evaluated through testing the compressive strength of blended cement mortars. The results indicate that red mud calcinated at 600⁰C has good cementitious activity due to the formation of poorly-crystallized Ca₂SiO₄ [90].

Reduction of radioactive levels of red mud based ceramic materials was also studied. Self-glazing red mud based ceramic materials (RMCM) were produced by normal pressure sintering process using the main raw materials of red mud. The properties of the RMCM samples were investigated by the measurements of mechanical properties, radiation measurement, X-ray diffraction (XRD) and scanning electron microscopy (SEM) [73].

The hybrid composites reinforced by short fibres and nano-particulates were investigated. A new method for an inexpensive fabrication of bulk lightweight metal matrix nano composites (MMNCs) with reproducible microstructures and superior properties by use of ultrasonic nonlinear effects, namely transient cavitation and acoustic streaming, to achieve uniform dispersion of nano-sized SiC particles in molten aluminum alloy A356 [88].

The researchers were made an attempt to propose that the hardness of the alloy increases with the addition of hybrid reinforcements and the increase in hardness may be due to the presence of relatively hard ceramic particles in the composite. The effects of warm compaction on the green density and sintering behaviour of aluminium alloys were investigated [74-75]. Aluminium-MMCs by powder metallurgy using ceramic particles as reinforcements were investigated [43-44, 46-48, 94].

The characteristics were correlated with different aluminium metal matrix composites. The tensile deformation and fracture behaviour of aluminium alloy 2014 discontinuously-reinforced with particulates of Al_2O_3 was studied with the primary objective of understanding the influence of reinforcement content on composite microstructure, tensile properties and quasi-static fracture behaviour. The injection of powders in the form of MMCs leads to considerable improvement in incorporation and distribution of Al_2O_3 particulates in the Aluminium matrix alloy leading to the improvement in tensile properties. Improvement in tensile properties is attributed to the better wetting of Al_2O_3 by melt as well as removing micro channels and roughness on alumina particles as a consequence of ball milling process [81-82].

The impact of nano size particles on metal matrix composites was studied [90]. The hybrid composites offer more flexibility and reliability in the design of possible components depending upon the reinforcement's combination and compositions were studied. The feasibility and viability of developing low cost-high performance hybrid composites are used for automotive and aerospace applications. Further, the fabrication characteristics and mechanical behavior of Hybrid aluminum matrix composites (HAMCs) fabricated by stir casting route have also been reviewed [75].

Red mud (RM) is a hazardous waste produced vastly by aluminum industry worldwide. Because of its rich metal oxide content, it has potential to be utilized in various applications, such

as ceramics production, construction, and catalysis. The structural modification of red mud by simple acid treatments using HCl and H₂SO₄ at different molarities, and at different digestion temperatures followed by calcinations at various temperatures were performed [78]. The removed red mud and soil mixture (RMSM) was transferred into the reservoirs for storage. In this paper the application of RMSM is evaluated in a field study aiming at re-utilizing waste, decreasing cost of waste disposal and providing a value-added product [28].

Structures before and after these treatments were characterized in deep detail by combining electron microscopy, diffraction, and spectroscopy complemented by thermal analysis and mass spectrometry to elucidate any changes in morphology, structure, and chemical composition introduced by these treatments. Many studies have proved that the presence of particulate reinforcements can tremendously influence the mechanical and wear behaviour of aluminium metal matrix composites. Red mud of micro level particulates reinforced aluminium metal matrix composites have demandable attention in recent years, due to their excellent mechanical and tribological capabilities using stir casting process [50].

The tribological behaviour of a commercial low-metallic friction material during dry sliding against a pearlitic cast iron has been investigated and the evolution of pin and disc temperature was recorded. The temperature distributions in the pin and the disc were modelled using a finite element analysis with three different approaches, i.e. considering a perfect contact, the separated bodies concept, and the presence of a third body between the sliding surfaces. The results were then discussed by considering the damaging phenomena occurring at the sliding contact. Wear was found to be nearly mild in nature in agreement with the contact temperatures that were determined to be lower than 100 °C.

In addition, literature studies also tell that most of the published work has recommended aluminium-based composites with their attractions of low density, heat treatment capability and processing flexibility [48]. Al matrix composites reinforced with Ti₃AlC₂ and Cu coated Ti₃AlC₂ were prepared by hot-press sintering approach. It was confirmed that Ti₃AlC₂ displayed poor wettability with Al, resulting in the poor interfacial bonding strength between Ti₃AlC₂ and Al matrix. However, Al₂Cu layer could be formed due to the reaction between Cu and Al during the

sintering process, when Cu coated Ti_3AlC_2 was incorporated in Al matrix. Because of the formation of enhanced Al_2Cu interface, the mechanical and tribological properties were significantly improved.

Even though large numbers of researchers have worked on the experimental investigation of metal matrix composites, only a few researchers have attempted metal matrix hybrid composites at micro and nano level. The present work is focussed on the mechanical and wear behaviour of red mud at micro and nano level with tungsten carbide particle reinforced in aluminium through conventional sintering.

2.5 GAP ANALYSIS

After thoroughly going through the literature, aluminium with red mud of micro level only reinforced metal matrix composites with stir casting process is available. Some of the major limitations in the existing literature on metal matrix hybrid composites with micro and nano level are given as below:

- i. There is no attempt made to investigate on nano level red mud reinforced in aluminium metal matrix composites through powder metallurgy route.
- ii. There is no attempt made to study on red mud and tungsten carbide reinforced in aluminium metal matrix hybrid composites.
- iii. There is no studies are made for evaluation of experimental compression stress values with Deform-2D simulation software on aluminium-red mud and aluminium-red mud-tungsten carbide metal matrix hybrid micro as well as nano composites.
- iv. Mathematical relations to predict the hardness and wear behaviour of aluminium with micro and nano red mud has not presented.
- v. The impact of heat treatment conditions on aluminium-red mud and aluminium-red mud-tungsten carbide metal matrix hybrid micro as well as nano composites at normal condition and heat treatment conditions have not been reported.
- vi. To predict the hardness and wear behaviour of aluminium with micro and nano red mud with tungsten carbide after heat treatment using regression analysis, mathematical modeling has not been presented.

2.6 MOTIVATION OF THE WORK

Presently it has been difficult for the industries to dispose of their wastage and utilisation of by-products. The huge amount of industrial byproducts/wastes is becoming clients for increasing environmental pollution and generation of a huge amount of unutilized resources. The present research work is aimed at finding out the solution of utilising the industrial byproducts for value-added applications and also makes easier to solve the environmental problems. Aluminium is the second most widely used metal in the world, after the iron. Red mud is one of the wastages produced during manufacturing of alumina. For every 2.5 tonnes of alumina production, 1.5 tonnes of red mud is produced [42, 54, 76, 79]. The application of red mud as a basic catalyst for biodiesel production and manufacturing of ceramic tiles are studied [59, 95]. The evolution of red mud is shown in Figure 2.1.

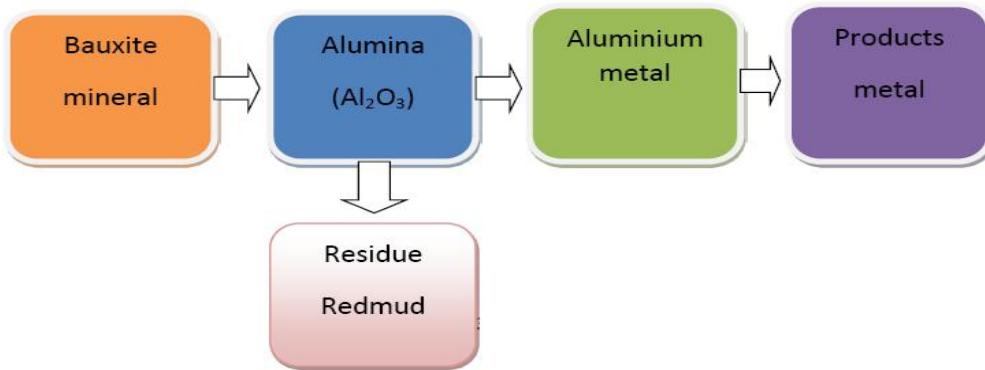

Figure 2.1: Evolution of red mud

More than 4 million tonnes of red mud is generated annually only in India. Presently, it is stored or dumped on land, or in the oceans near alumina refineries. It is a potential pollution problem to threat water, land and air due to its high alkalinity nature [45, 91]. While high costs are associated with the large area of land required for storage of the residue [93]. India is amongst the major producers of alumina in the world. The effects of red mud on the environment are shown in Figure 2.2 and 2.3. There are some differences in mineralogical composition between the residues from India and other countries due to the difference in the ore type in its production processes.

Figure 2.2: Water polluted by red mud Figure 2.3: Sun flower plants destroyed by red mud

2.7 OBJECTIVES AND SCOPE OF RESEARCH WORK

Depend on the limitations of the available information in literature review concerning aluminium metal matrix composites, the current investigation is formulated to study the mechanical characterization, micro structural observations and tribological behaviour of red mud and tungsten carbide particle reinforced in aluminium metal matrix nano composites.

In general, the objectives of the current investigation are as follows: To investigate the use of red mud (bauxite residue) as a reinforcing material as a low-cost option.

- 1) To investigate the best weight fraction of red mud as reinforcing material required in the aluminium metal matrix composites for optimum properties.
- 2) To evaluate the merits of nano red mud reinforcement over micro red mud reinforcement.
- 3) To explore mechanical behaviour and determine the hardness at normal and heat treatment conditions validate with mathematical modeling using Regression Analysis, compression test and validation of compression test with Deform -2D software.
- 4) To evaluate the effect of tribological behaviour of micro and nano red mud reinforced in aluminium metal matrix composites.

- 5) To investigate the heat treatment effect on micro and nano red mud and tungsten carbide reinforced in aluminium metal matrix hybrid composites.
- 6) To develop mathematical equations that predict the hardness, wear rate of micro and nano red mud and tungsten carbide reinforced in aluminium metal matrix hybrid composites at normal and heat treatment temperatures.

2.8 PROBLEM FORMULATION / METHODOLOGY

The present research work is aimed at determining the utilisation of industrial byproducts for value-added applications and also makes easier to solve the environmental problems. The continuous demand for reinforcement materials improved the interest towards utilization of bauxite residue (red mud) which contains major elements like iron oxide (Fe_2O_3), Al_2O_3 , Na_2O and TiO_2 etc., to aluminium and tungsten carbide for making the metal matrix hybrid composites especially for wear resistant applications. An attempt has been made in the current work, red mud is mixed with other metals mainly aluminium and tungsten carbide to form hybrid metal matrix composites synthesised by powder metallurgy.

- 1) Preparation of the nano red mud using high energy ball milling and X-Ray Diffraction (XRD) analysis is to be carried out.
- 2) Mixing and compacting the pure aluminium powder with micro and nano level red mud and tungsten carbide.
- 3) Evaluation of conventional sintering process for the samples of pure aluminium, red mud and tungsten carbide metal matrix hybrid micro as well as nano composites.
- 4) Conducting hardness tests at normal and heat treatment conditions and compression tests validated by Deform-2D software with compressive stress at 10%, 20% and 30% reduction.
- 5) Adopting micro structural observations based on Scanning Electron Microscope (SEM) and Energy Dispersive X-Ray spectroscopy (EDX).
- 6) Conducting wear tests on pin-on-disc wear testing equipment for evaluating wear behaviour before and after heat treatment conditions.
- 7) Employing regression analysis approach with for various processing conditions of the hardness, wear rate of micro and nano red mud and tungsten carbide reinforced in aluminium metal matrix hybrid composites at normal and heat treatment temperatures.

2.9 OVERALL RESEARCH PLAN

The overall research plan is shown in Figure 2.4.

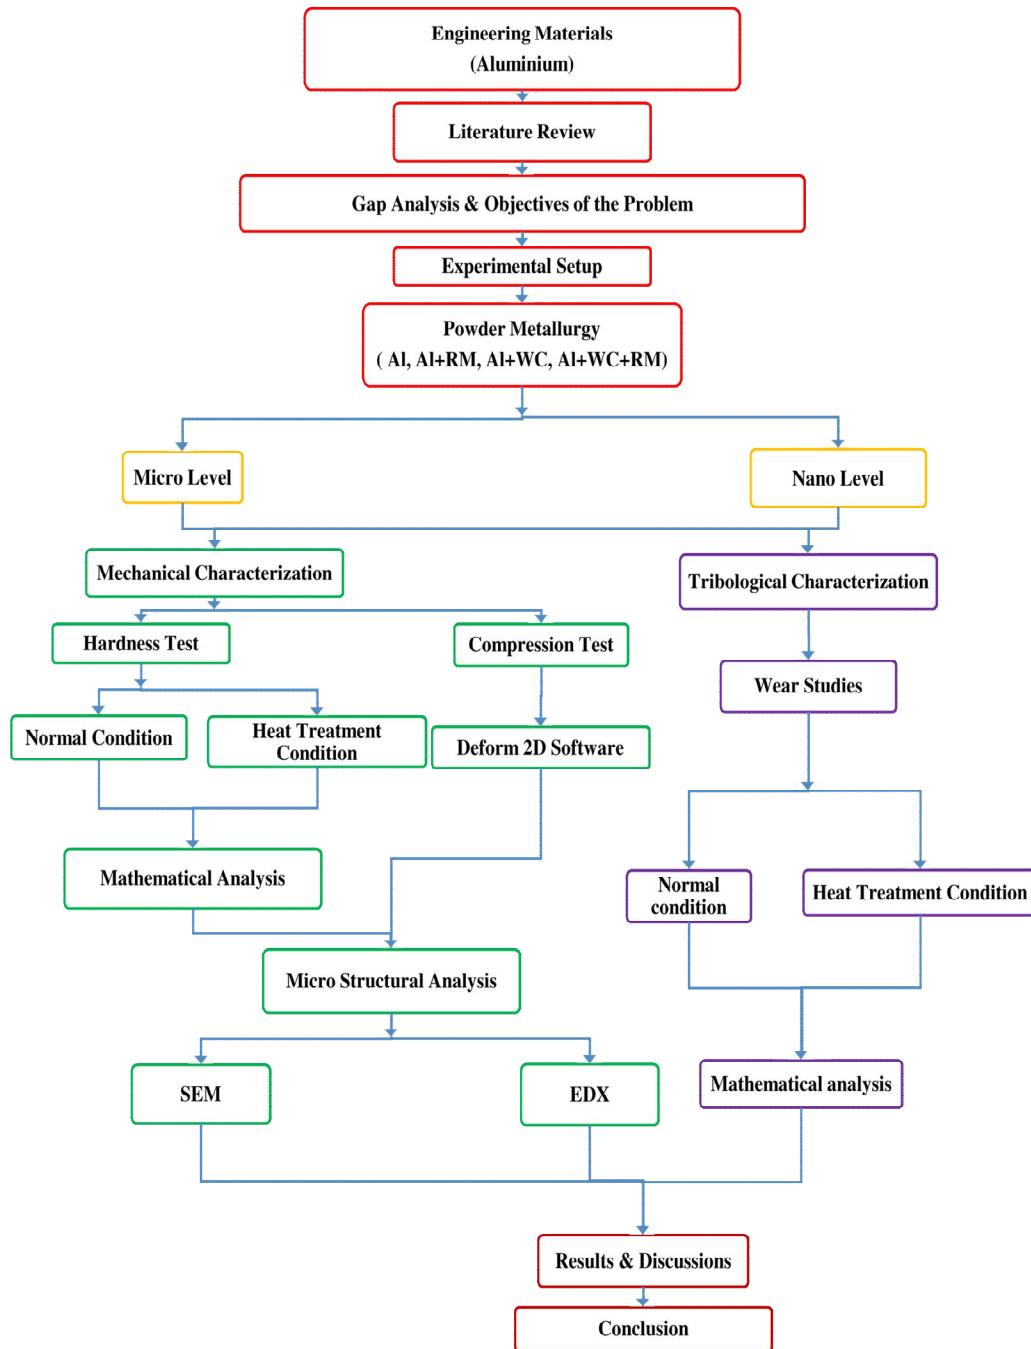

Figure 2.4: Overall research plan

2.10 SUMMARY

In this chapter, earlier works related to aluminium composites and aluminium hybrid composites are briefly presented. The significance of engineering materials and their applications are also discussed. From the literature review, most of the work has completed on aluminium metal matrix composites and very few of researches have studied on aluminium hybrid metal matrix composites. This chapter gives the information about gap analysis, the motivation of the work, objectives and scope of the research work, problem formulation and methodology of the current research work. The overall research plan of the thesis is also presented.

CHAPTER-3

EXPERIMENTAL SET UP

3.1 INTRODUCTION

The present chapter is describing the selection of raw materials, preparation of nano level red mud, aluminium-red mud metal matrix composites and aluminium- red mud- tungsten carbide metal matrix hybrid composites used in this experimental work. Pure aluminum is taken as matrix material. Red mud and tungsten carbide are used as reinforcements. The Red mud material is subjected to high energy ball milling and converted into nano structured powder. The nano structured red mud has been characterized for its structure by X-ray diffraction studies [29]. The high-energy ball mill is typically used to produce particles in the nano scale size range. The standard mill for conducting mechanical attrition experiments is Pulverisette which is referred to as the planetary ball mill [30, 82-86].

3.2 SELECTION OF MATERIALS

The material used in this experimental work is finely pulverized, pure aluminum powder of 99.72% purity. The aluminum powder is used to prepare aluminium-red mud and aluminium-red mud-tungsten carbide sintered compacts of aspect ratio i.e. height to diameter ratio 0.5 with a die size of 15 mm diameter and 30 mm height.

3.2.1 Sieve analysis

Sieve analysis (or gradation test) is a procedure used to assess the particle size distribution of a granular material. The red mud used for the present investigation is collected from the National Aluminum Company Limited (NALCO) Damanjodi, Odisha, India. The chemical compositions of pure aluminum powder, red mud and tungsten carbide are shown in Table 3.1, 3.2 and 3.3 respectively.

Table 3.1: Chemical composition of pure aluminum

Element	Fe	Si	Mg	Cu	Zn	Mn	Al
Wt%	0.17	0.07	0.001	0.005	0.003	0.0008	0.75

Table 3.2: Chemical composition of red mud

Element	Fe ₂ O ₃	Al ₂ O ₃	SiO ₂	Na ₂ O	TiO ₂	Sc	MnO	CaO	K ₂ O	Sr	MgO	V ₂ O ₅
Wt%	53.8	14.3	8.34	4.3	3.9	3.2	2.95	2.5	2.25	2.45	1.63	0.38

Table 3.3: Chemical composition of tungsten carbide

Element	W	Cr	Si	B	C	Mg
Wt%	4.5	2.42	1.71	0.8	0.5	0.07

The received red mud is subjected to sieve analysis using mechanical sieve shaker for collecting particles of uniform sizes of 100, 150, and 200 microns for preparing the micro sized red mud powder.

3.3 HIGH ENERGY BALL MILLING

Nano particles are formed in a mechanical device known as high energy ball mill referred to as pulverisette for conducting mechanical attrition experiments which are shown in Figure 3.1. The planetary high energy ball mill has its name which implies the planet-like rotation of its vials. These vials are arranged on a rotating support disk, and drive mechanism causes them to rotate around their own axes. The centrifugal force produced by these vials rotating around their own axes and that produced by the rotating support disk both act on the vial contents, consisting of material to be ground and the grinding balls. Since the vials and the supporting disk rotate in opposite directions, the centrifugal forces alternately act in like and opposite directions. The reduction in particle size of red mud from micron level to the nano level is carried out using a high-energy planetary ball mill in a stainless steel chamber using tungsten carbide of 10 mm Φ balls size. The balls of 10 mm diameter tungsten carbide are used to crush the micro-size red mud powder into nano-size red mud powder in ball milling. The micron-sized red mud powder is milled for 30 hours by maintaining the rotation speed of the planet carrier at 200 rpm. The ball mill is loaded with the ball to powder weight ratio (BPR) of 10:1. Toluene is used as the medium

with an anionic surface active agent to avoid agglomeration. The preparation of nano red mud is shown in Figure 3.2.

Figure 3.1 Pulverisette - High energy ball mill

Figure 3.2 Preparation of nano red mud

3.4 X-RAY DIFFRACTION (XRD) ANALYSIS

The milled sample red mud powder is taken out after 6 hours, 13 hours, 24 hours and 30 hours of high energy ball milling and dried with mechanical drier. The X-Ray Diffraction (XRD) testing machine was carried out at IIT, Madras (Figure 3.3).

Figure 3.3: X-Ray Diffraction (XRD) testing machine

The X-Ray Diffraction (XRD) Patterns for 0 hours, 6 hours, 13 hours, 24 hours and 30 hours are shown in Figures 3.4 to 3.8. It is clearly observed that the intensity of the peaks in the XRD pattern got reduced and the peak broadening increased as the duration of milling increases. Fe_2O_3 was observed in XRD given for 6 hours milled red mud. The peak labels are strongly placed in Figures 3.4-3.8. Due to high energy ball milling, the elements of NaTiO_2 which were combined with other elements in the red mud powder after 24 hours of milling. The fine nano red mud powder is obtained after 30 hours.

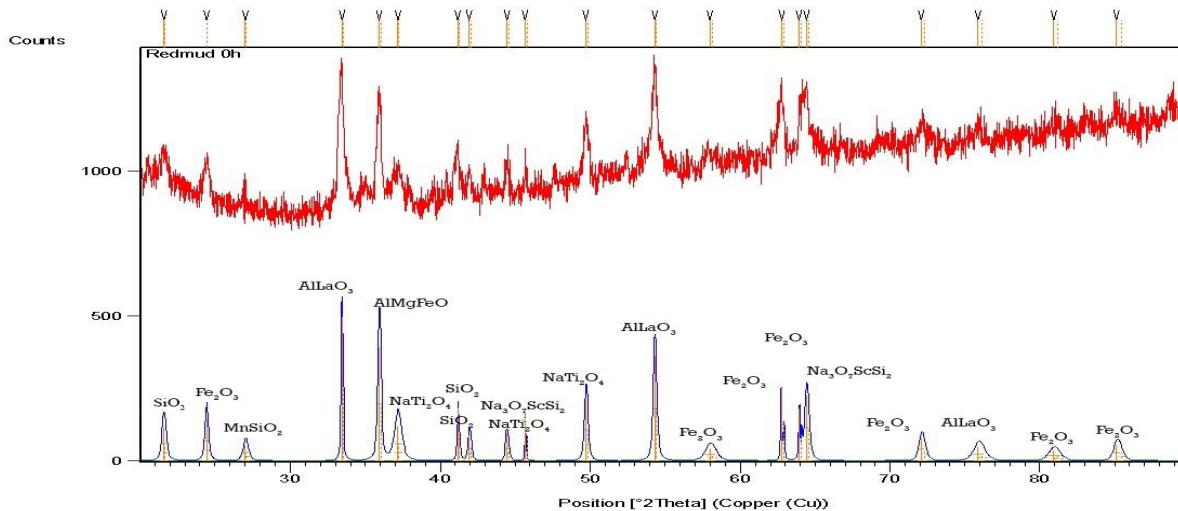

Figure 3.4: XRD Pattern for 0 hours milled red mud

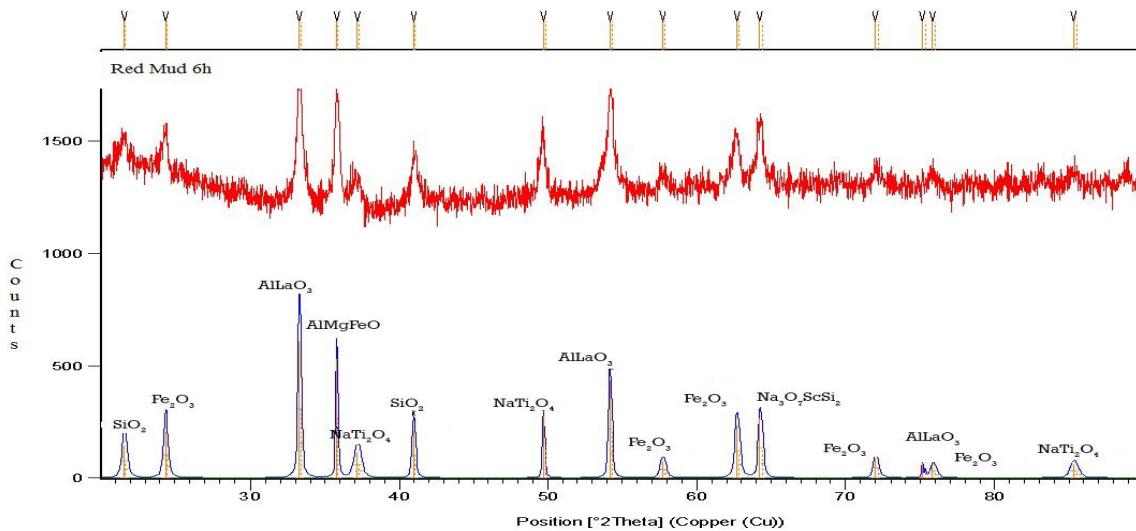

Figure 3.5: XRD Pattern for 6 hours milled red mud

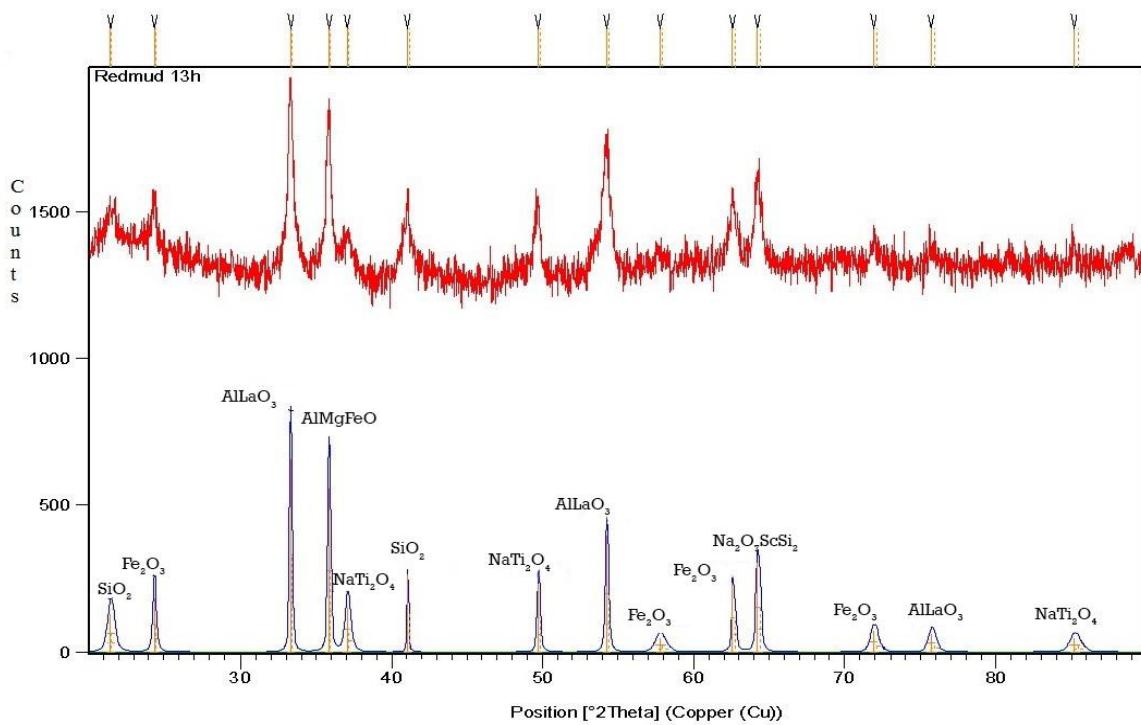

Figure 3.6: XRD Pattern for 13 hours milled red mud

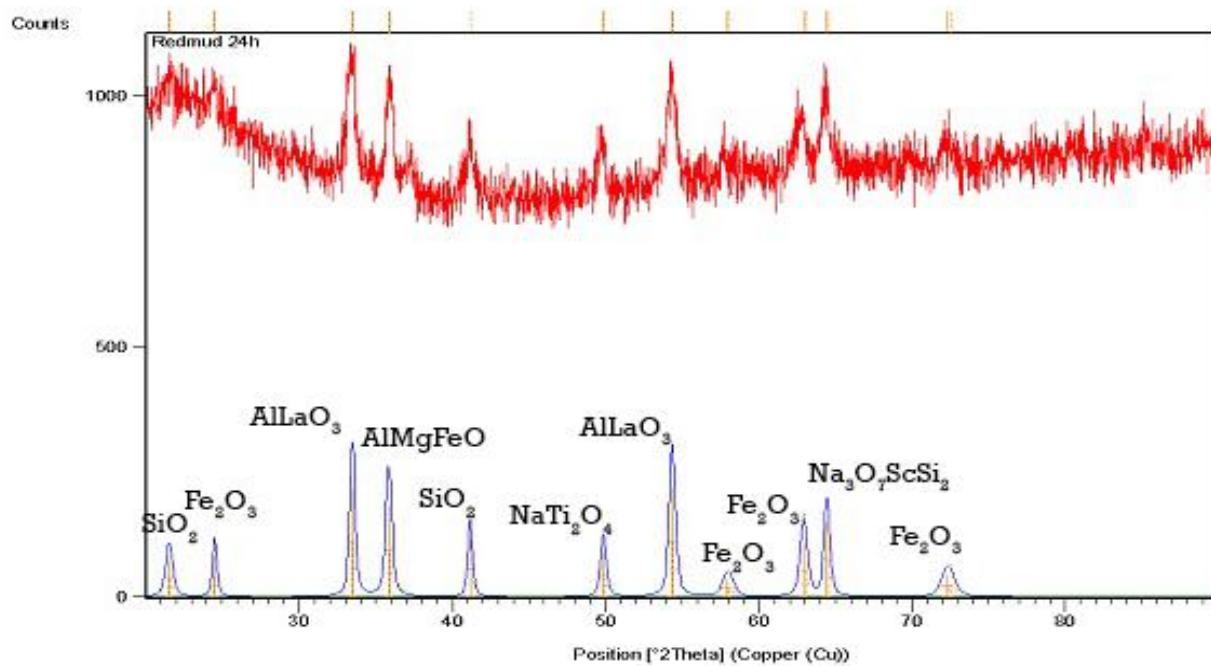

Figure 3.7: XRD Pattern for 24 hours milled red mud

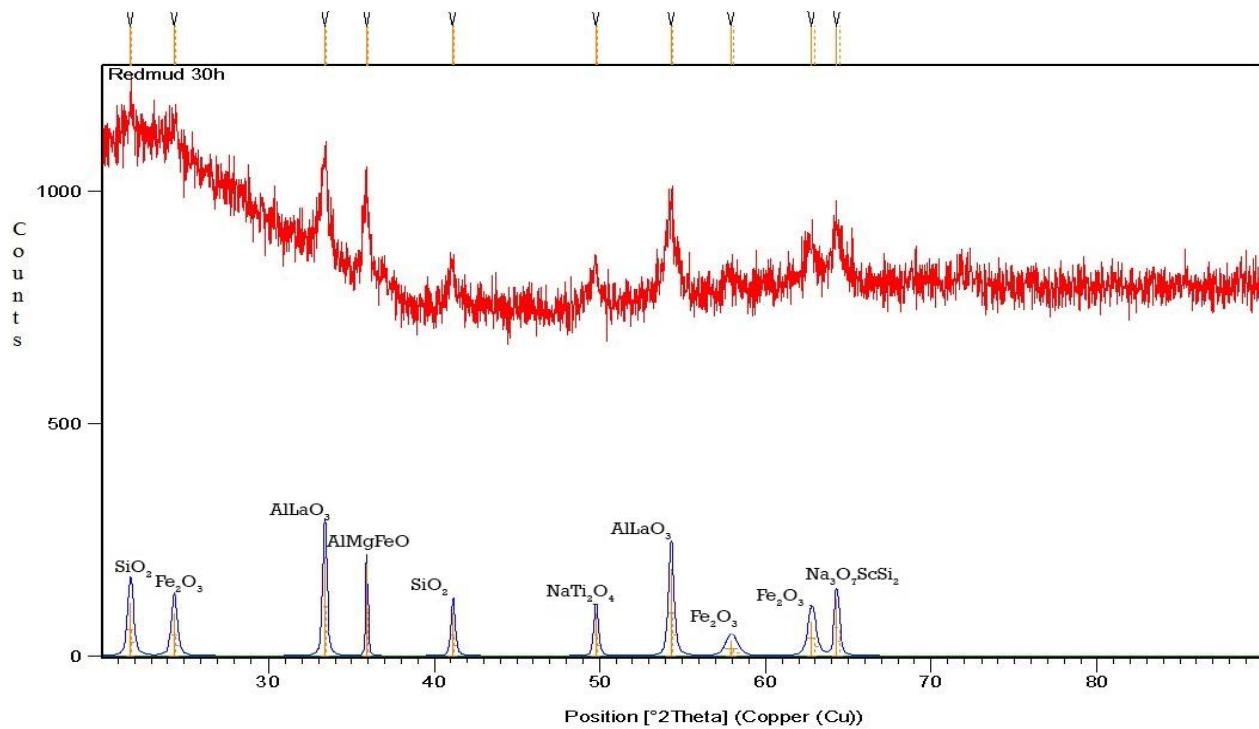

Figure 3.8: XRD Pattern for 30 hours milled red mud

The most widely used equation to determine grain size from XRD data is the Scherrer equation as $L_0 = k\lambda / (\beta \cos\theta)$ 3.1

where K is a constant of order 1 dependent on particle shape,

λ is the wavelength of the X-ray radiation,

θ is the diffraction angle and

β is the peak full width at half-maximum (FWHM),

The evaluation of nano particle size for XRD Pattern at 30 hours milled red mud powder is shown in Figure 3.9. The XPert HighScore Plus software is used to analyse the particle size of red mud after 30 hours of high energy ball milling. The particle size of 42 nm ($418 \text{ \AA}^0 = 41.8 \text{ nm}$) is obtained after 30 hours of high energy ball milling using Scherrer Calculator which is shown in Figure 3.9.

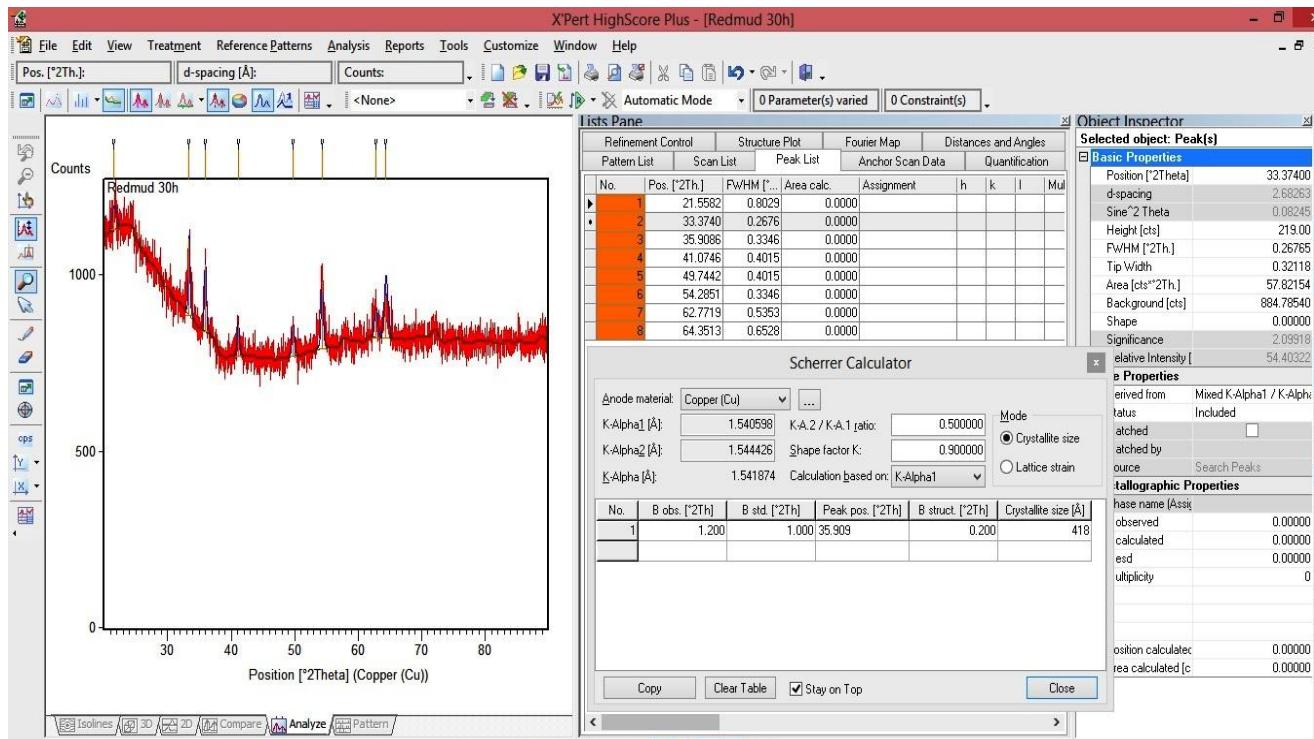

Figure 3.9: Evaluation of nano particle size for XRD Pattern at 30 hours milled red mud

The mean or average size of the crystallite sizes should be displayed by the Scherrer Calculator as 418 Å⁰ in XRD –analysis software of X’Pert High Score Plus for 30 hours milled red mud powder shown in the above Figure 3.9.

3.5 CONVENTIONAL SINTERING THROUGH POWDER METALLURGY

3.5.1 Mixing and Compacting

The micro level red mud powders of 100 µm, 150 µm and 200 µm and nano level red mud powder of 42 nm are used at 2%, 4% and 6% of weight fractions with pure aluminium powder. These mixtures are blended in a double cone mixer which is shown in Figure 3.10 for 10 hours in order to obtain proper mixing of particles with each other [28].

The different proportions of aluminium-red mud sample materials are compacted in a hydraulic press of 100 ton load capacity which is shown in Figure 3.11. During compacting, the applied pressure and compact pressing time were 40 bar and 10 seconds respectively. The pure aluminum powder at 2%, 4%, and 6% weight fractions of red mud at 100 microns size as well as 42 nano meters along with 4% weight fraction of tungsten carbide powder of 5 microns size are also prepared.

3.5.2 Sintering and manufacturing of composite preparation

Sintering is a thermal treatment process, which transforms a metallic or ceramic powder (or a powder compact) into a bulk material below the melting temperature of the main constituent material. The Vacuum sinter furnace is manufactured by ACME (Advanced Corporation for Materials and Equipments), China. The Model No ZSJ-25x25x50 with a loaded weight of 50 kg and loaded vacuum of 4×10^{-3} Pa. The temperature of the sintering furnace is raised up to 1550°C with a heating power capacity of 50kW. In the Figure 3.12, the sintering machine is shown and sintering is performed in a vacuum chamber. The compacted pure aluminum and red mud

samples in the sintering furnace are shown in Figure 3.13. The aluminium-red mud and aluminium-red mud-tungsten carbide hybrid metal matrix micro level and nano level sintered samples are prepared.

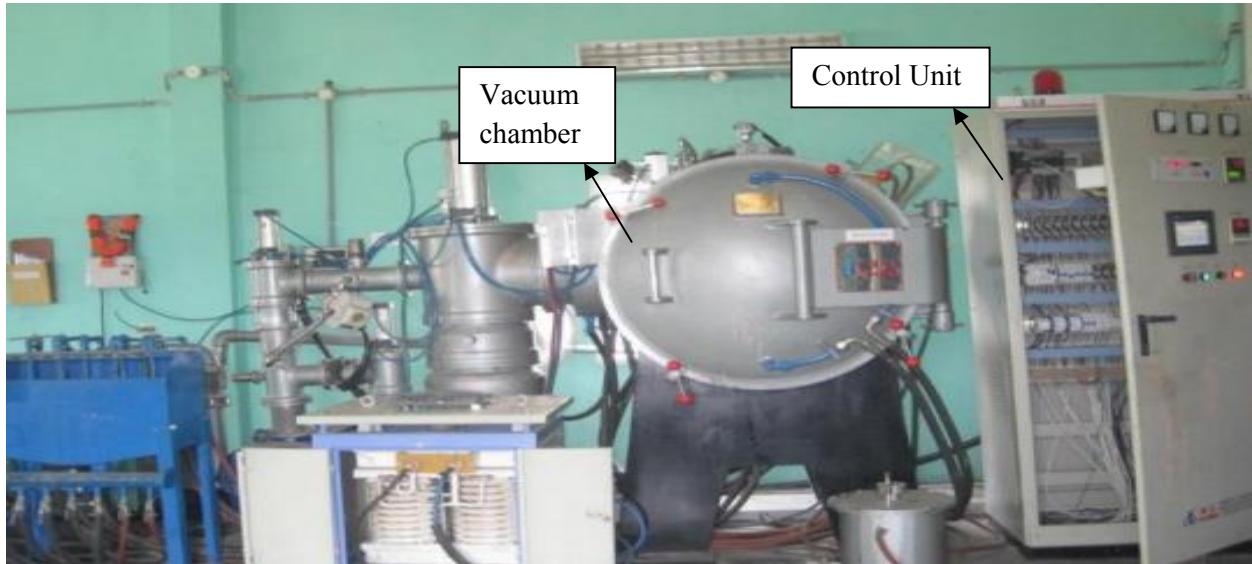

Figure 3.12: Sintering Machine

The vacuum maintained during sintering is 250 Pa (using a compressor of 1.5 H.P) and the temperature is raised to 300^0C in 30 minutes and soaked at 300^0C for 30 minutes. To avoid oxidation and maintain vacuum, Argon gas medium is used to evacuate the air in the sintering chamber. Adhesive bonding is obtained inside the sintering samples. The temperature is further raised to 500^0C in 35 minutes and again soaked at 500^0C for 30 minutes. Then cooling is done to room temperature in 3 hours. Hence the total sintering cycle time was 5 hours 5 minutes. The XRD pattern for pure aluminium and 6% nano red mud sintered sample which has $\text{Al-Al}_3\text{Fe}$, AlFe_2Mn and $\text{Fe}_4\text{Mn}_{72}\text{Si}_{19}\text{CuO}$ phases are shown in Figure 3.14.

Figure 3.13: Compacted Pure Aluminium and Red mud samples in Sintering Furnace

The XRD pattern for pure aluminium with 4% tungsten carbide and 6% nano red mud sintered sample which has $\text{AlFe}_3\text{V}_2\text{O}_5\text{W}_2\text{C}$, AlFe_2Mn , W_2C , $\text{AlFe}_2\text{O}_3\text{TiO}_2\text{W}_2\text{C}$ and $\text{Fe}_2\text{O}_3\text{MnSiO}_2$ phases are shown in Figure 3.15.

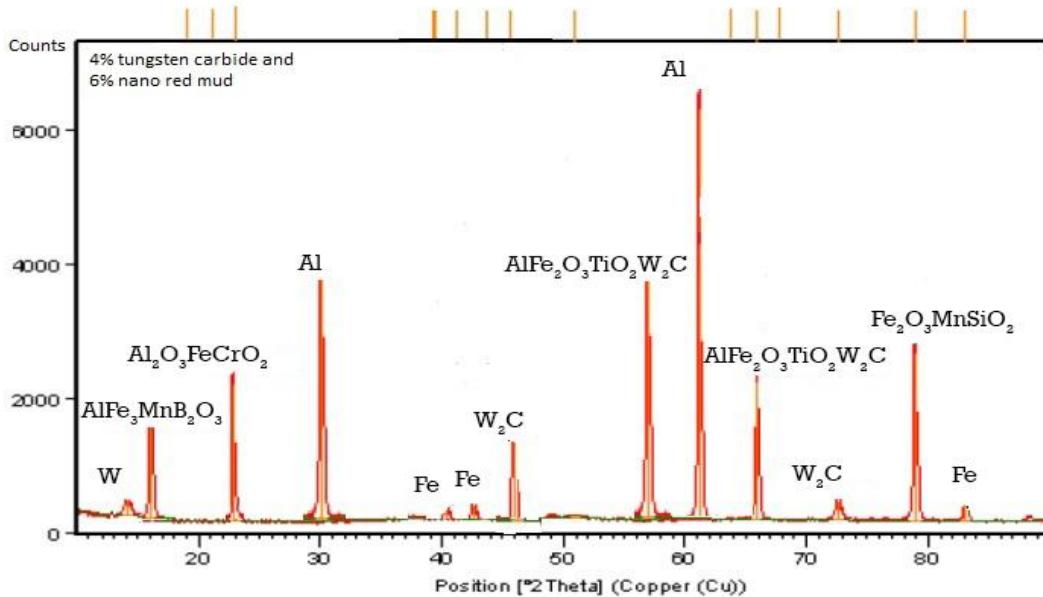

Figure 3.15: XRD pattern for pure aluminium with 4% tungsten carbide and 6% nano red mud sample after Sintering

3.6 RESULTS

The red mud powder with particle size of 100, 150 and 200 at micron level and 42 at nano level are prepared. The aluminium with the red mud of 2%, 4% and 6% weight fractions with 100 μm , 150 μm , 200 μm and 42 nm and aluminium with red mud and tungsten carbide of 2%, 4% and 6% weight fractions with 100 μm and 42 nm samples are prepared through conventional sintering.

The fresh red mud powder particles after 30 hours of high energy ball milling at 42 nm are in irregular shapes and the surface morphology is rough. The relative lattice strain is increasing with increasing the duration of milling time. The XPert- HighScore Plus software is used for analysing the X-Ray Diffraction (XRD) data which shows the lattice strain increases whenever milling time increases from 0 hours to 30 hours. This lattice strain is increased from 0.12 to 0.28 after 30 hours of high energy ball milling. The particle size of 42 nm is obtained after 30 hours of high energy ball milling.

3.7 SUMMARY

This chapter gives the information about the selection of materials, sieve analysis, high energy ball milling and X-Ray Diffraction (XRD) analysis at 0 hours, after 6 hours, 13 hours, 24 hours and 30 hours of high energy ball milling. It provides the details about conventional sintering through powder metallurgy for sample preparation. It also gives the information about mixing, compacting and sintering machine.

CHAPTER-4

MECHANICAL CHARACTERIZATION

4.1 INTRODUCTION

The present chapter is describing mechanical characterization of pure aluminium with red mud, pure aluminium with red mud and tungsten carbide. The mechanical properties such as hardness and compression strength are evaluated using Micro Vickers hardness testing machine and compression testing machine respectively. The mathematical prediction is done for hardness values using regression analysis.

4.2 HARDNESS TEST AT NORMAL CONDITION

Hardness values are measured using Micro Vickers Hardness tester according to ASTM E-32. The Vickers Hardness Number (VHN) is given by $1.854L/d^2$ where L is known as the applied load in kgf and d is known as diagonal length of a square impression in mm. The hardness results for aluminium- red mud metal matrix composites at normal condition are shown in Table 4.1. The graph between hardness and percentage (%) weight fraction of red mud with pure aluminium at normal condition is shown in Figure 4.1.

Table 4.1: Hardness results for aluminium-red mud metal matrix composites at normal condition

Aluminium with % weight fraction of Red mud(RM)	Particle size	Hardness (VHN)
Pure Al	45 μ m	47.4
Al+2% RM	100 μ m	60.2
Al+4% RM	100 μ m	67.6
Al+6% RM	100 μ m	74.5
Al+2% RM	150 μ m	58.3
Al+4% RM	150 μ m	62.4
Al+6% RM	150 μ m	69.2
Al+2% RM	200 μ m	56.7
Al+4% RM	200 μ m	59.3
Al+6% RM	200 μ m	63.5
Al+2% RM	42 nm	73.6
Al+4% RM	42 nm	77.4
Al+6% RM	42 nm	83.9

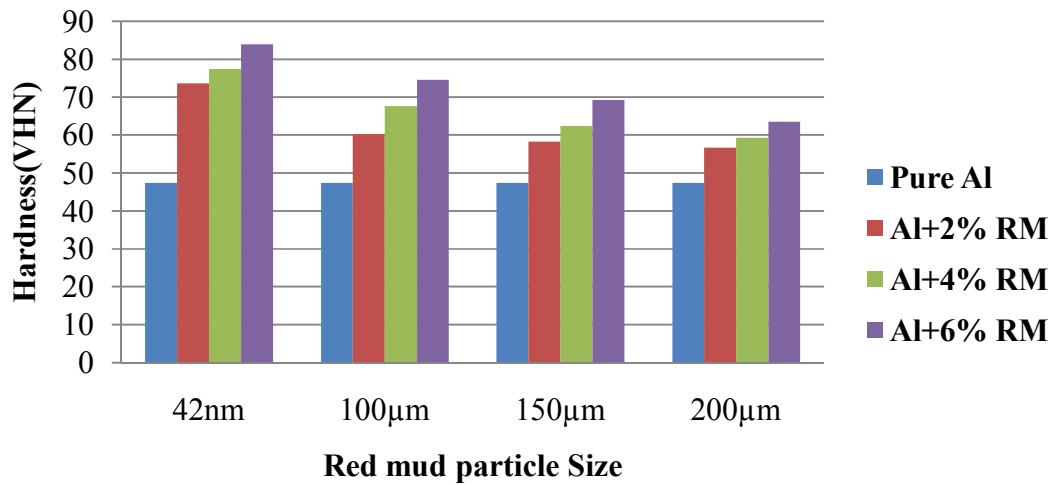

Figure 4.1: Hardness Vs % weight fraction of red mud with pure aluminium at normal condition

It is observed that, for the same percentage weight fraction of red mud, the hardness is higher for the nano level reinforcement than micro level reinforcement. The hardness results for aluminium- red mud-tungsten carbide metal matrix composites at normal condition are shown in Table 4.2. The graph between hardness and % weight fraction of red mud and 4% tungsten carbide with pure aluminium at normal condition is shown in Figure 4.2.

Table 4.2: Hardness results for aluminium-red mud-tungsten carbide metal matrix composites at normal condition

Aluminium and 4% WC with % weight fraction of Red mud(RM)	Particle size	Hardness (VHN)
Al+4% WC	45 μm	47.70
Al+4% WC +2% RM	100 μm	62.35
Al+4% WC + 4% RM	100 μm	68.74
Al+4% WC +6% RM	100 μm	75.23
Al+4% WC +2% RM	42 nm	75.43
Al+4% WC +4% RM	42 nm	79.21
Al+4% WC +6% RM	42 nm	84.90

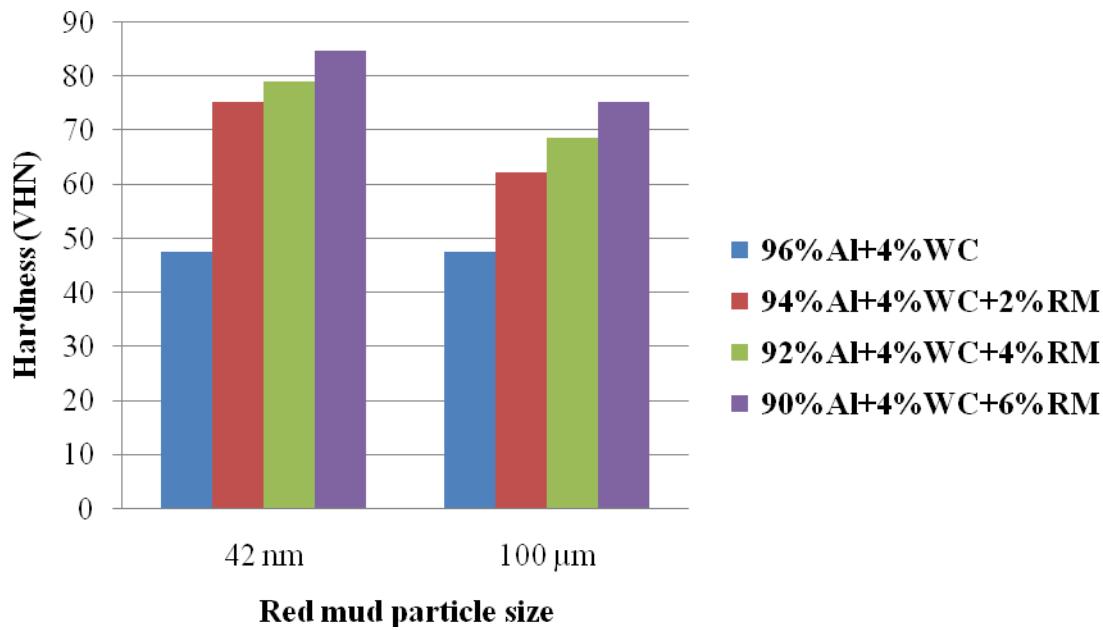

Figure 4.2: Hardness Vs % weight fraction of red mud and 4% tungsten carbide with pure aluminium at normal condition

Porosity analysis is conducted and obtained as 87% and 89% of Al+Red mud and Al+Red mud+WC metal matrix composites respectively. It is observed that the 6% nano level red mud with pure aluminium and 4% tungsten carbide has better hardness value of 84.9 VHN compared to remaining proportions. Aluminium, red mud and tungsten carbide hybrid metal matrix composites have shown better hardness compared to aluminium with red mud metal matrix composites. As percentage weight fraction composition of red mud increases, hardness values are also increases. Since the red mud consists of ferrous oxide as its major constituent about 53.8% and harder in nature. Finer particles are strongly bonded to each other in nano-sized red mud powder and improved the surface hardness compared with the micro-sized red mud powder.

4.3 HARDNESS TEST FOR HEAT TREATMENT CONDITIONS

The effects of heat treatment on mechanical properties of aluminium cast alloys are studied [22]. In the present work, heat treatment is carried out for the hardness results of pure aluminium and aluminium-red mud metal matrix composites at heat treatment conditions of 350^0C , 400^0C , 450^0C and 500^0C are conducted and shown in Table 4.3. The graphs between

hardness and percentage (%) weight fraction of red mud with pure aluminium at heat treatment conditions of 350^0C , 400^0C , 450^0C and 500^0C are shown from Figure 4.3-4.6.

Table 4.3: Hardness results for aluminium-red mud metal matrix composites at heat treatment conditions

Aluminium with % weight fraction of Red mud(RM)	Particle size	Temperature (^0C)	Hardness (VHN)
Pure Al	45 μm	350	48.6
Al+2% RM	100 μm	350	62.7
Al+2% RM	42 nm	350	74.3
Al+4% RM	100 μm	350	68.7
Al+4% RM	42 nm	350	81.8
Al+6% RM	100 μm	350	77.1
Al+6% RM	42 nm	350	85.4
Pure Al	45 μm	400	50.4
Al+2% RM	100 μm	400	64.3
Al+2% RM	42 nm	400	76.8
Al+4% RM	100 μm	400	69.7
Al+4% RM	42 nm	400	83.6
Al+6% RM	100 μm	400	79.3
Al+6% RM	42 nm	400	88.9
Pure Al	45 μm	450	51.2
Al+2% RM	100 μm	450	66.8
Al+2% RM	42 nm	450	79.6
Al+4% RM	100 μm	450	73.1
Al+4% RM	42 nm	450	87.5
Al+6% RM	100 μm	450	82.4
Al+6% RM	42 nm	450	95.7
Pure Al	45 μm	500	50.7
Al+2% RM	100 μm	500	65.7
Al+2% RM	42 nm	500	77.4
Al+4% RM	100 μm	500	71.9
Al+4% RM	42 nm	500	85.2
Al+6% RM	100 μm	500	80.8
Al+6% RM	42 nm	500	88.5

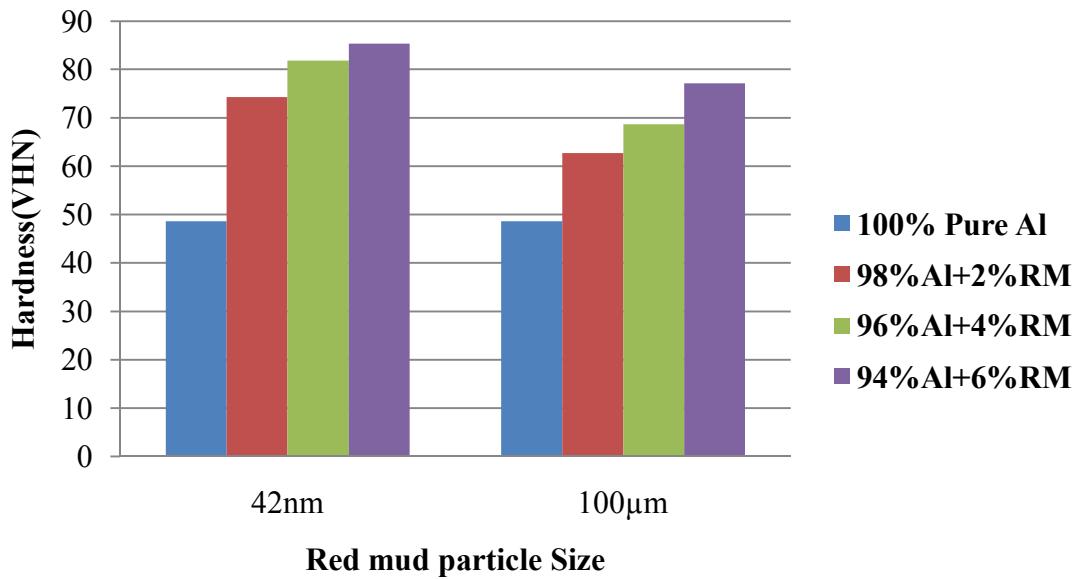

Figure 4.3: Hardness and % weight fraction of red mud with pure aluminium at 350°C

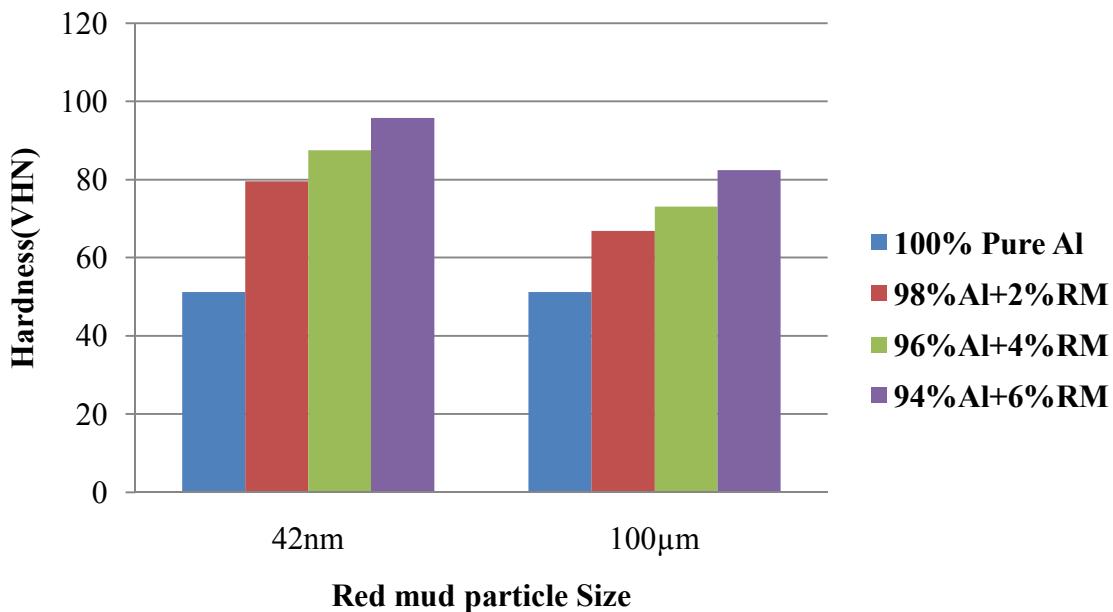

Figure 4.5: Hardness and % Weight fraction of red mud with pure aluminium at 450°C

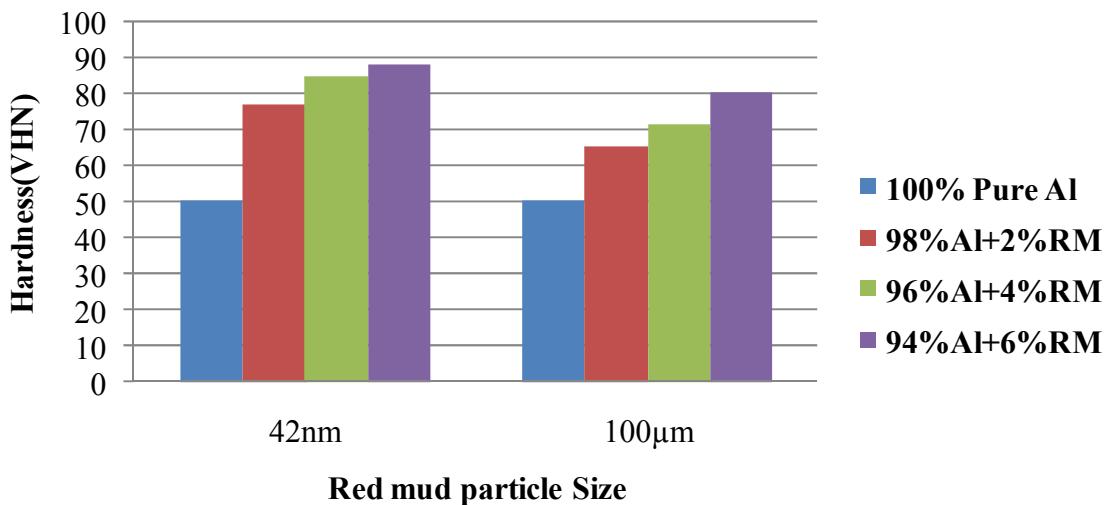

Figure 4.6: Hardness and % Weight fraction of red mud with pure aluminium at 500°C

It is observed that nano level (42nm) red mud possessed better hardness compared to micro level (100μm) red mud with aluminium metal matrix composites at heat treatment conditions as shown in Figure 4.3- 4.6. It is observed that the hardness is more with increase in the amount of percentage weight fraction from 2% to 6% of red mud. The hardness results for aluminium-red mud-4% tungsten carbide metal matrix hybrid composites at heat treatment

conditions of 350^0C , 400^0C , 450^0C and 500^0C are conducted and shown in Table 4.4. The plots between hardness and percentage (%) weight fraction of red mud with pure aluminium and 4% tungsten carbide at heat treatment conditions of 350^0C , 400^0C , 450^0C and 500^0C are shown from Figure 4.7-4.10.

Table 4.4: Hardness Results for Aluminium-Red mud-Tungsten Carbide metal matrix composites at heat treatment conditions

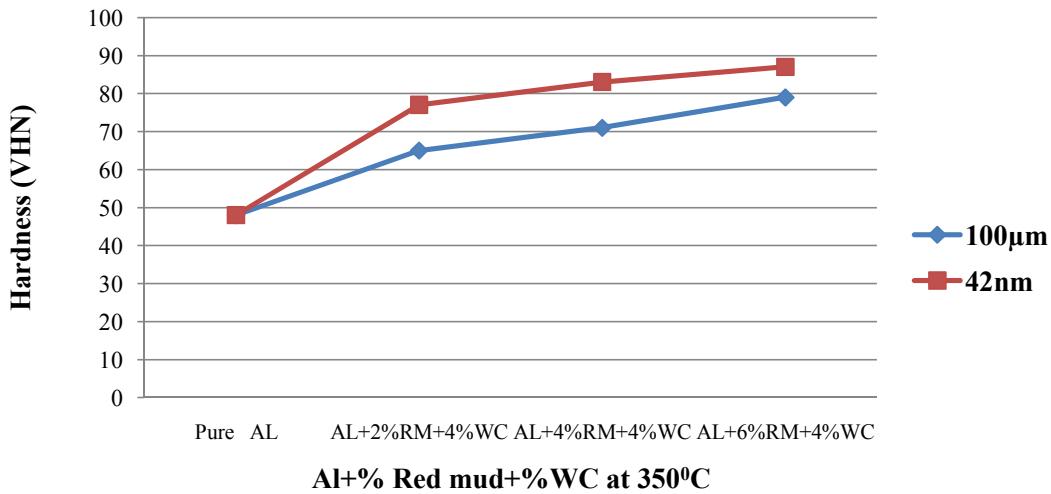

Figure 4.7: Hardness Vs % weight fraction of red mud and 4% tungsten carbide with pure aluminium at 350°C

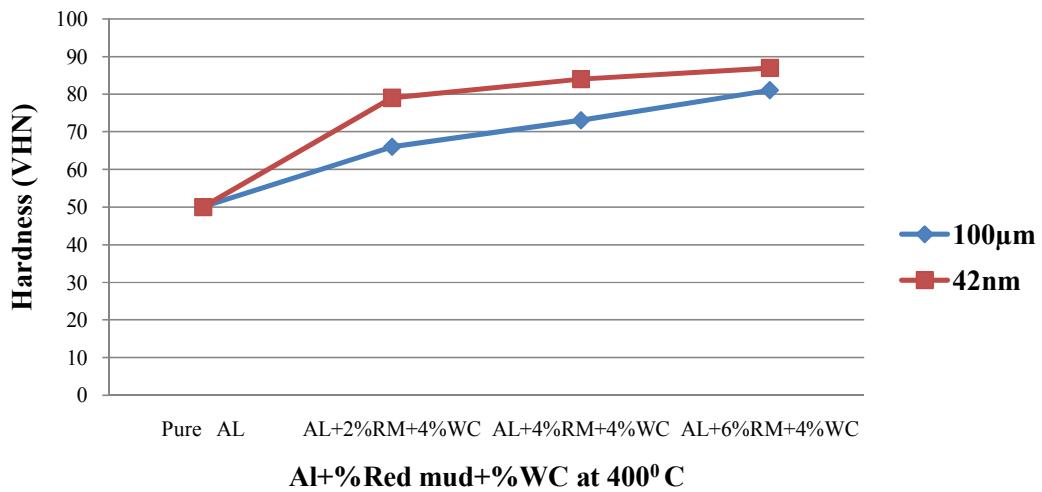

Figure 4.8: Hardness Vs % weight fraction of red mud and 4% tungsten carbide with pure aluminium at 400°C

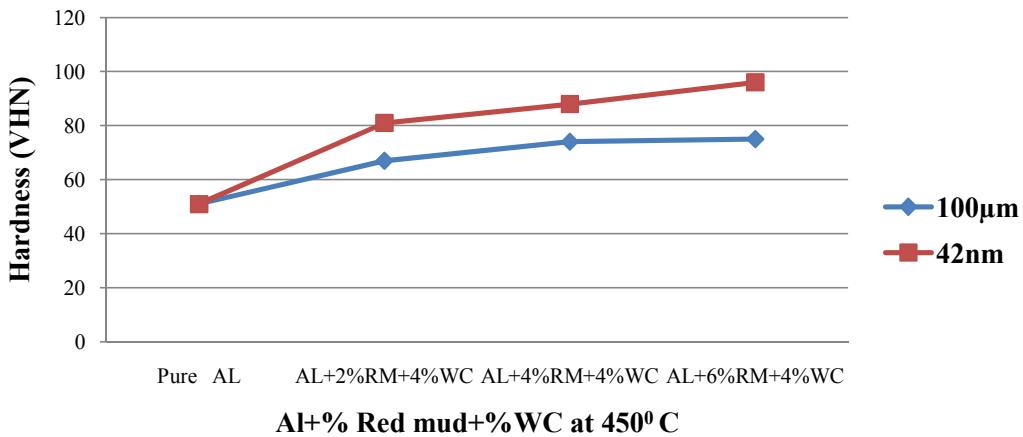

Figure 4.9: Hardness Vs % weight fraction of red mud and 4% tungsten carbide with pure aluminium at 450°C

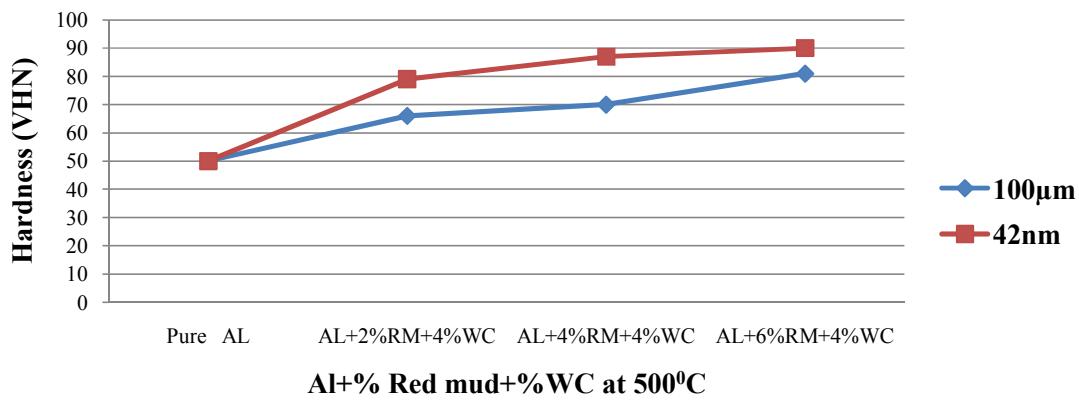

Figure 4.10: Hardness Vs % weight fraction of red mud and 4% tungsten carbide with pure aluminium at 500°C

It has been observed that the hardness values are improved up to 450°C, after that there is a decrement in hardness values. In heat treatment conditions, hardness values are higher for the nano level reinforcement than micro level reinforcement compared to normal condition. This is resulted because of the increase in surface area of contact and higher bond strengths. The excessive heat generated at the disc-pin interface may cause thermal stresses. Under the highest load applied, the mating material raised the specimen temperature could cause oxidation of contact surfaces. The oxide films were brittle and easily smashed in the wear process. These

oxide debris were embedded in the specimen surface by the contact load which enhanced its bond strength, hardness and increased its wear resistance. This is so called glazed hardening.

4.4 MATHEMATICAL MODELING BY REGRESSION ANALYSIS

A mathematical model is developed using regression analysis for the hardness values of aluminium and red mud. The overall equations at normal condition and heat treatment conditions (350^0C , 400^0C , 450^0C and 500^0C) are shown in equations 4.1 and 4.2 respectively. Here particle size, percentage weight fraction of red mud and temperature are taken as random variables for evaluating the linear relationship between hardness and these parameters.

$$\text{Hardness} = 67.149 + [(2.64375) \times \text{particle size}] - [(0.00339) \times \text{percentage weight fraction of red mud}] \quad (4.1)$$

$$\text{Hardness} = 47.9363 + [(5.5625) \times \text{percentage weight fraction of red mud}] - [(0.09041) \times \text{particle size}] + [(0.0256) \times \text{temperature}] \quad (4.2)$$

It has been observed that the R-square values for equations 1 and 2 are 0.9717 and 0.8849 from regression statistics as shown in Figure 4.11.

Figure 4.11: Regression statistics of Hardness results for pure aluminium and red mud at heat treatment condition

Regression analysis in the context of sensitivity analysis involves fitting a linear regression to the model response and using standardized regression coefficients as direct measures of sensitivity. The regression is required to be linear with respect to the data (i.e., hyperplane hence with no quadratic terms etc as regressors). Therefore, this method is most suitable when the model response is linear. The regression analysis has the advantage of simple and low computational cost.

A mathematical model is developed using regression analysis for the hardness values of aluminium, red mud and tungsten carbide. The overall equations at normal condition and heat treatment conditions (350^0C , 400^0C , 450^0C and 500^0C) are shown in equations 4.3 and 4.4 respectively.

$$\text{Hardness} = 59.9167 - [(0.08311) \times \text{particle size}] + [(4.37475) \times \text{percentage weight fraction of red mud}] \quad (4.3)$$

$$\text{Hardness} = 55.9024 - [(0.08422) \times \text{particle size}] + [(4.5149) \times \text{percentage weight fraction of red mud}] + [(0.02113) \times \text{temperature}] \quad (4.4)$$

It has been observed that the R-square values for equations 3 and 4 are 0.8861 and 0.8883 from regression statistics as shown in Figure 4.12.

Figure 4.12: Regression statistics of Hardness results for pure aluminium, red mud and tungsten carbide at heat treatment condition

In statistical modeling, regression analysis is a statistical analysis for estimating the relationships among variables. It includes many techniques for modeling and analyzing several variables when the focus is on the relationship between a dependent variable and one or more independent variables (or predictors). More specifically, regression analysis illustrates that how the typical value of dependent variable or criterion variable changes when any one of the independent variables is varied, while the other independent variables are held fixed.

Most commonly, regression analysis estimates the conditional expectation of the dependent variable given the impact of independent variables. Regression analysis is used to measure the “Goodness of Fit” that how well the calculated co-efficient which tells the calculated linear regression equation fits the input data. In the Figure 4.12, Multiple R is 0.9425, the correlation coefficient tells that strength of the linear relationship. R-squared is the coefficient of determination. It tells that how many points fall on the regression line. For example 80% means that 80% of the variation of y-values around the mean are explained by the x-values. In other words, 80% of the values fit the model. In the Figure 4.12, R square is 0.88 i.e., 88% of the values fit the regression model. The Adjusted R square is 0.8763, which adjusts more than one x-variable for the regression model.

An estimate of the standard deviation of the error ‘ μ ’. The standard error of the regression is the precision that the regression co-efficient is measured. If the co-efficient is large compared to the standard error, then the co-efficient is probably different from 0. In the Figure 4.12, the standard deviation of the error is 4.17. Therefore the regression model exhibits results with 1-4% error difference. In the Figure 4.12, the number of observations in the sample are 32. After 450^0C , aluminium was started to reach the melting temperature of 660^0C and reduced the adhesive bonding between matrix and reinforcement materials.

4.5 COMPRESSION TEST

Compression strength values were calculated experimentally at 10, 20, and 30 percent reduction using compression testing machine as shown in Figure 4.13 and validated using Deform-2D software. The compressive stress for pure aluminium and pure aluminium with 2%, 4% and 6% weight fractions of $100\mu\text{m}$, $150\mu\text{m}$ and $200\mu\text{m}$ red mud particle size at 10%, 20%

and 30% reduction using Deform-2D software are shown in Appendix-I. The compressive stress for pure aluminium with 2% and 4% weight fraction of red mud (42 nm) at 10%, 20% and 30% reduction using Deform-2D software are also shown in Appendix-I. In this present chapter, the compressive stress for pure aluminium with 6% weight fraction of red mud (42 nm) at 10%, 20% and 30% reduction using Deform-2D software are shown from Figure 4.14 to 4.16.

Figure 4.13: Compression testing machine

4.6 VALIDATION OF COMPRESSION TEST WITH DEFORM -2D SOFTWARE

The compressive stress for pure aluminium with 6% weight fraction of red mud (42 nm) at 10% reduction using Deform-2D software is shown in Figure 4.14. The effective stress value is 58.2 MPa.

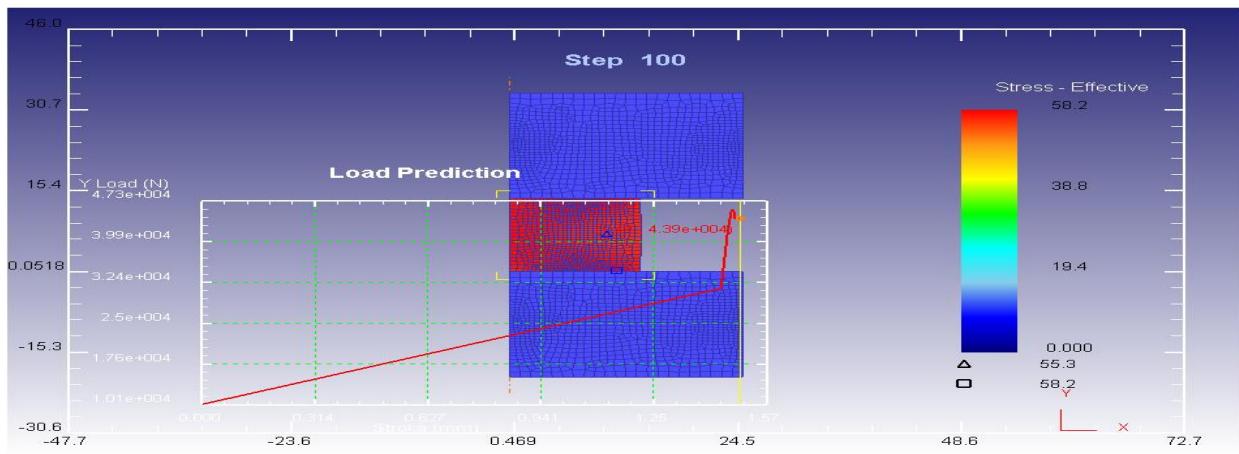

Figure 4.14: Compressive Stress for aluminium with 6% weight fraction of red mud (42 nm) at 10% reduction using Deform-2D software

The compressive stress at 20% and 30% reduction for pure aluminium with 6% weight fraction of red mud (42 nm) using Deform-2D software are shown in Figure 4.15 and 4.16 respectively and the effective stress values are 92.1 MPa and 98.4 MPa.

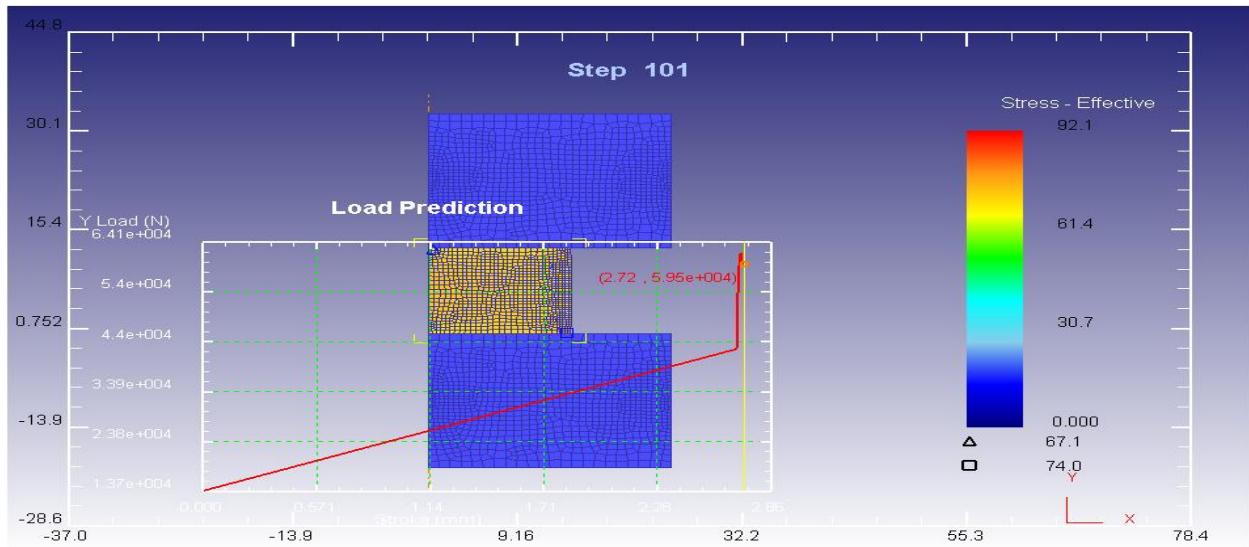

Figure 4.15: Compressive Stress for aluminium with 6% weight fraction of red mud (42 nm) at 20% reduction using Deform-2D software

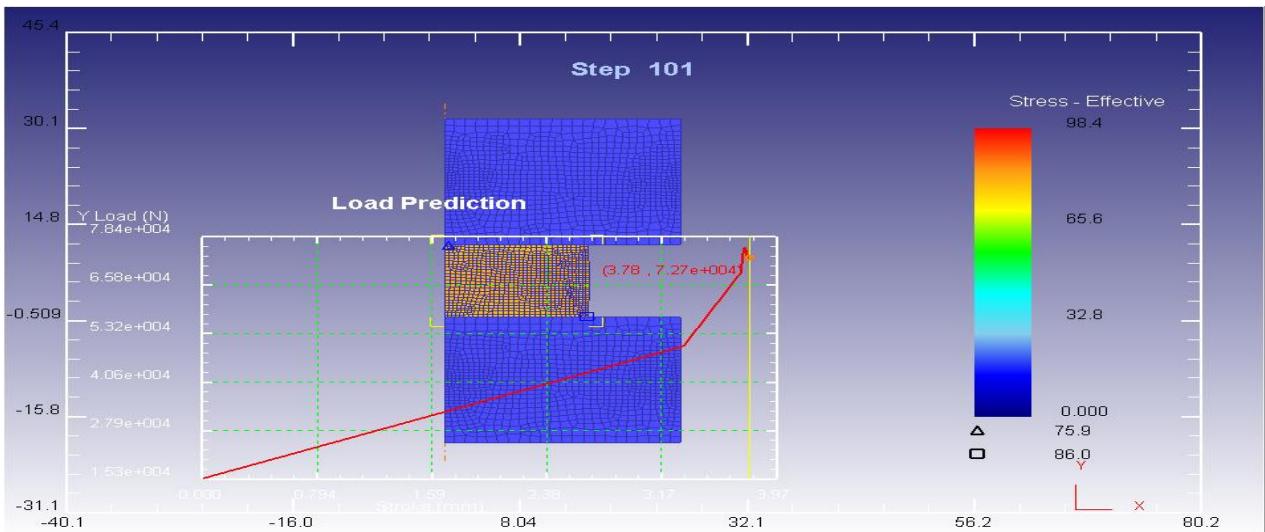

Figure 4.16: Compressive stress for aluminium with 6% weight fraction of red mud (42 nm) at 30% reduction using Deform-2D software

4.6.1 Overall Compression test results with Deform -2D Software

Both experimental and Deform-2D simulated compressive stress values are shown in Table 4.5.

Table 4.5: Experimental and Deform-2D simulated compressive stress results

s.no	%Wt. of RM	Particle size of RM	Stress at 10% reduction			Stress at 20% reduction			Speed at 30% reduction		
			Experimental Result (MPa)	Simulation Result (MPa)	Error(%)=(Experimental-simulated)x100(experimental simulated)	Experimental Result (MPa)	Simulation Result (MPa)	Error (%)	Experimental Result (MPa)	Simulation Result (MPa)	Error (%)
1	2	100 μ m	52.6	48.9	7.03	76.8	75.2	2.08	84.5	81.5	3.55
2	2	150 μ m	52.1	48.3	7.29	75.2	74.1	1.46	83.9	81	3.46
3	2	200 μ m	51.4	47.3	7.98	74.6	72.8	2.41	82.6	80.3	2.78
4	2	42 nm	50.1	49.9	0.40	78.2	77	1.53	86.1	82.4	4.30
5	4	100 μ m	54.8	51.4	6.20	81.4	80.8	0.74	88.5	87.8	0.79
6	4	150 μ m	60.2	57.7	4.15	80.7	78.1	3.22	86.7	84.8	2.19
7	4	200 μ m	59.2	57.7	2.53	79.8	77	3.51	85.5	83.3	2.57
8	4	42 nm	62.9	62.3	0.95	82.3	76.4	7.17	90.9	89.6	1.43
9	6	100 μ m	71.5	70.3	1.68	91.4	89.7	1.86	97.3	96.4	0.92
10	6	150 μ m	58.3	56.2	3.60	89.7	85.9	4.24	95.1	93.2	2.00
11	6	200 μ m	57.3	54.5	4.89	86.6	84.7	2.19	94	91.7	2.45
12	6	42 nm	63.1	58.2	7.77	92.9	92.1	0.86	98.8	98.4	0.40

From the Figure 4.14 – 4.16, Appendix-I and Table 4.5, it has been observed that the compression strength values are higher for the 42nm particle size of red mud than 100 μm , 150 μm and 200 μm particle size of red mud with aluminium metal matrix composites. This is due to the better surface area of contact and higher bond strengths of nano particles.

4.7 MICRO STRUCTURAL OBSERVATIONS

4.7.1. Scanning Electron Microscope (SEM) Analysis

The micro structural observation for pure aluminium with 6% red mud and 4% tungsten carbide metal matrix composite of better hardness and compression strength sample is performed. The Scanning Electron Microscope (SEM) analysis for pure aluminium with 6% red mud and 4% tungsten carbide is analysed by JEOL, JSM-6610LV made in Japan having the particle dispersion of the given hybrid metal matrix composite. The SEM images of sintered pure aluminium with 6% red mud of 42 nm and pure aluminium with 6% red mud of 42 nm and 4% tungsten carbide are shown in Figure 4.17 and 4.18 respectively.

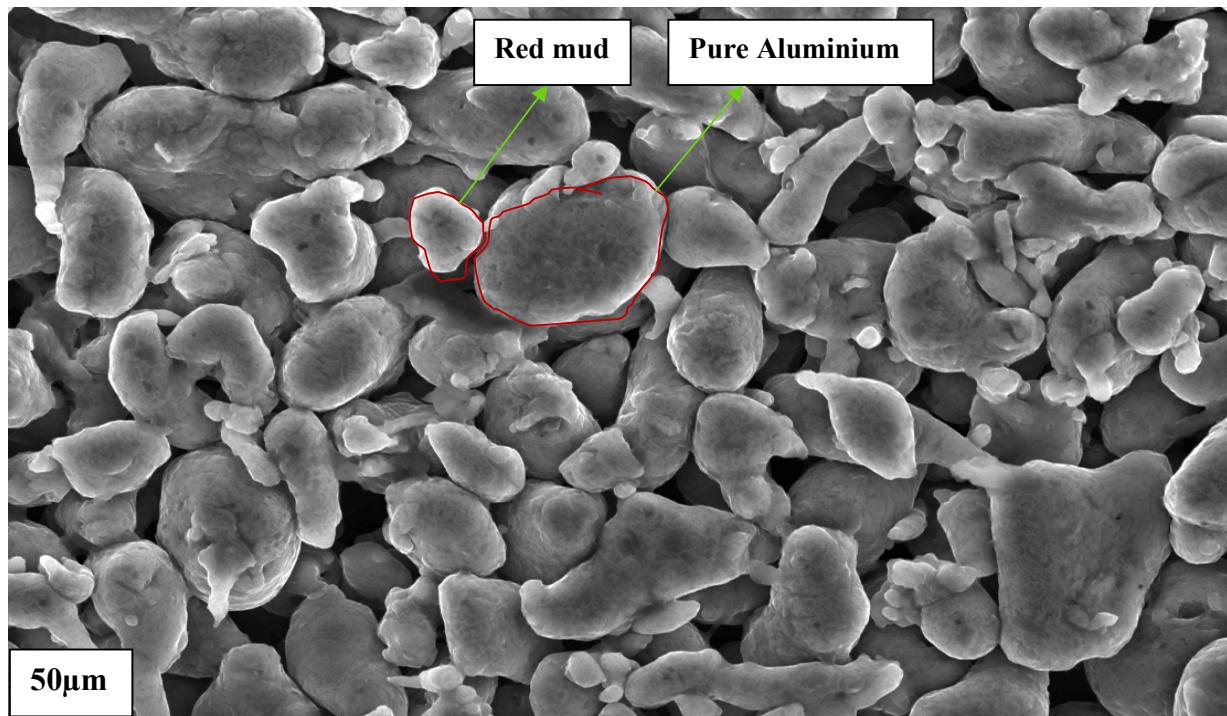

Figure 4.17: SEM analysis for sintered pure aluminium with 6% red mud (42 nm)

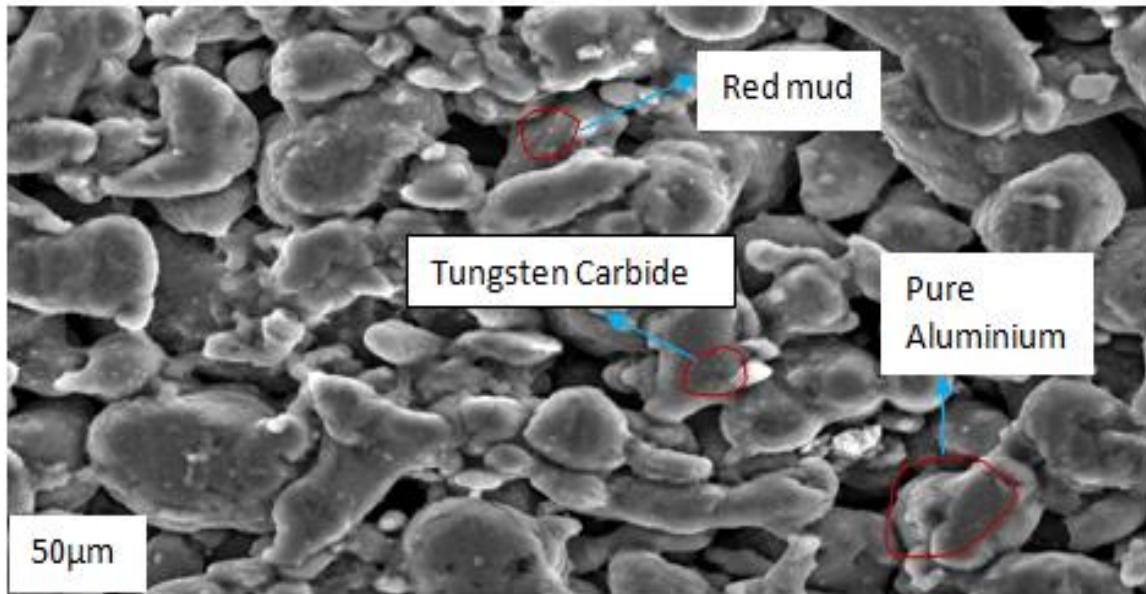

Figure 4.18: SEM analysis for sintered pure aluminium with 6% red mud (42 nm) and 4% tungsten Carbide

4.7.2. Energy Dispersive X-Ray Spectroscopy (EDX)

The Energy dispersive X-ray spectroscopy (EDX) analysis for pure aluminium with red mud and pure aluminium with 6% red mud and 4% tungsten carbide are shown in Figure 4.19 and 4.20 respectively by Inca Penta FET X3 of model no:7573 and resolution 129eV which is made by Oxford instruments.

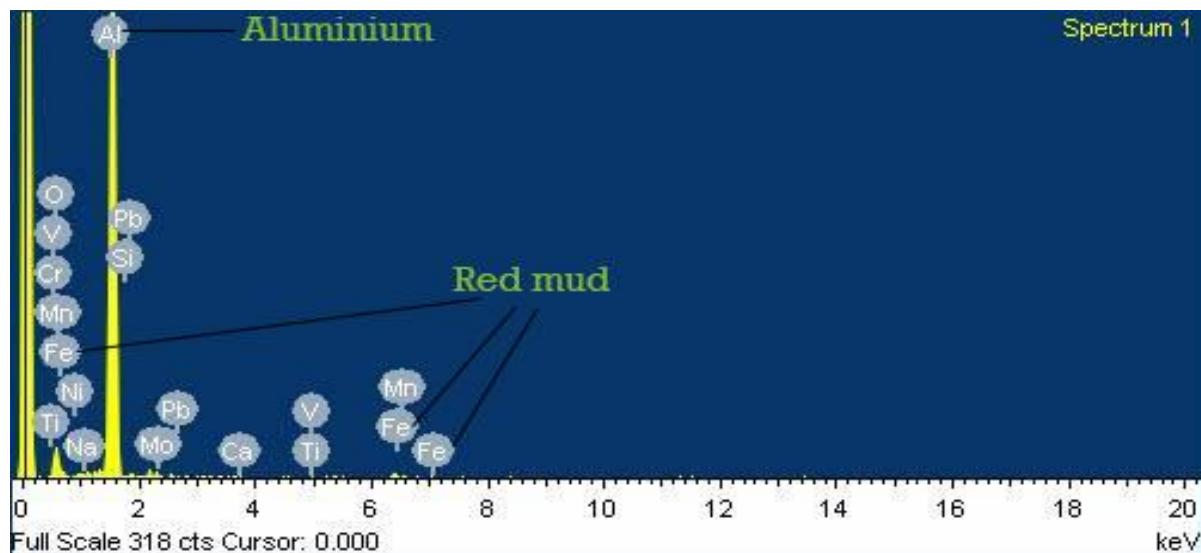

Figure 4.19: EDX analysis for pure aluminium with red mud

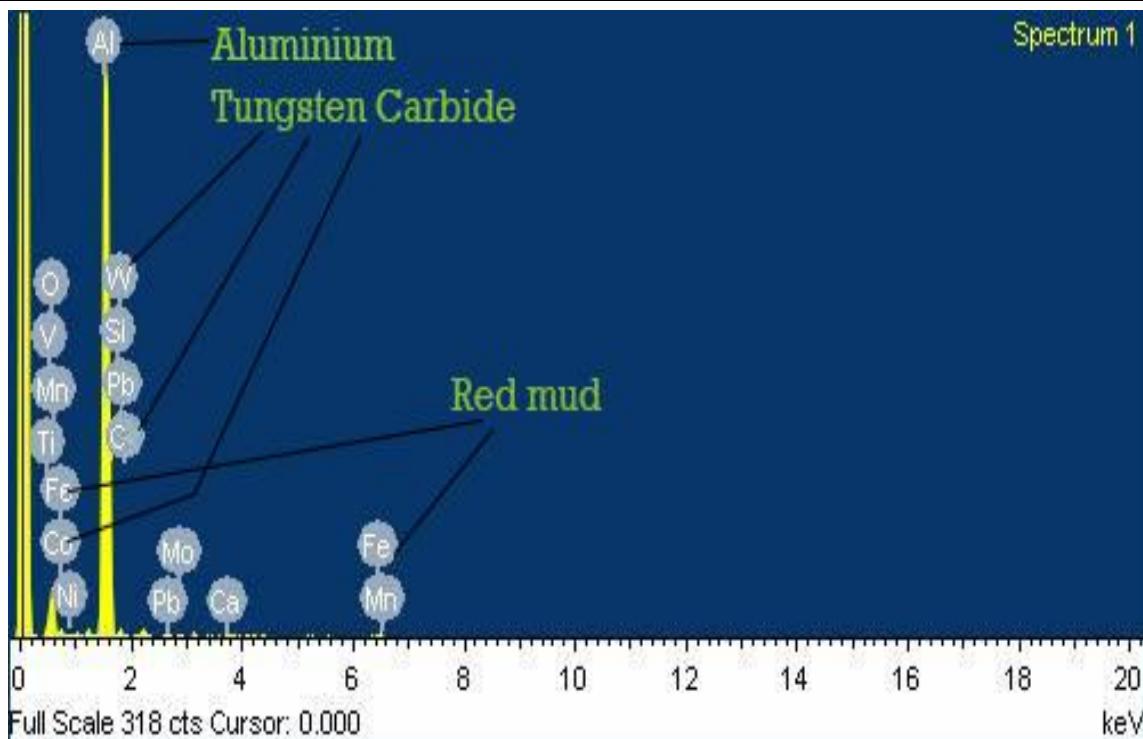

Figure 4.20: EDX analysis for pure aluminium with 6% red mud and 4% tungsten Carbide

4.8 RESULTS

- It has been observed that the hardness values variation depicts the information that nano red mud specimens have more hardness when compared with micro nature specimens. An increase in hardness and compression strength is observed for 6% weight fraction of nano level red mud.
- Since finer particles are strongly bonded to each other in a composite, the hardness and compression strength values of the nano composites are higher when compared to the micro level.
- It is also observed that for the same percentage weight fraction of red mud, the hardness and compression strength are higher for the nano structured reinforcement than micro structured reinforcement. This is owing to the increase in surface area of contact and higher bond strengths. Hardness and compression strength properties are improved for nano level aluminium-red mud test specimen with 42 nm size and 6% weight fraction of red mud.

- Initially, hardness increased with the addition of the tungsten carbide and then it is improved with an increment of the red mud. The simulated results of compression strength using Deform-2D software and experimental values are within the limits of 1-8% difference i.e., the % error is varied from 0.24 - 7.51 as shown in Table 4.5. Energy Dispersive X-ray spectroscopy (EDX) and Scanning Electron Microscope (SEM) structures are analysed to study the particle dispersion.
- A mathematical model is developed using regression analysis for the hardness values of aluminium with red mud and aluminium, red mud with tungsten carbide at normal and heat treatment conditions. The predicted equations are significant in nature with near unity R-square values.

4.9 SUMMARY

The present chapter gives the information regarding hardness test at normal condition and heat treatment conditions of pure aluminium, aluminium-red mud and aluminium-tungsten carbide-red mud of different weight fractions. The mathematical modeling is done by regression analysis. Compression test experimental results are validated using simulated Deform-2D software results and it has been observed that % error of both experimental and simulated values are close to each other. The micro structural observation such as Scanning Electron Microscope (SEM) analysis and Energy Dispersive X-Ray Spectroscopy (EDX) analysis are carried out.

CHAPTER-5

TRIBOLOGICAL CHARACTERIZATION OF PURE ALUMINIUM WITH RED MUD

5.1 INTRODUCTION

The present chapter is describing the tribological characterization of aluminium with red mud at normal and heat treatment conditions. The wear characteristics are investigated with an optimal combination of aluminium and 2%, 4% and 6% weight fractions of micro and nano level red mud metal matrix composites. Using regression analysis, the mathematical prediction is carried out for both normal and heat treatment conditions.

5.2 WEAR CHARACTERISTICS ANALYSIS AT NORMAL CONDITIONS

Experiments have been conducted in the pin-on-disc wear testing machine monitor with data acquisition system, which is used to evaluate the wear behaviour of the composite, against hardened ground steel disc (EN-32) having surface roughness (R_a) $0.5\mu\text{m}$. Sliding generally occurs between a stationary pin and a rotating disc. The disc rotates with the help of a D.C. motor having speed range 0-1000 rpm with wear track diameter 50 mm-80 mm, which could yield sliding speed 0 to 10 m/sec. The pin-on-disc wear testing machine is shown in Figure 5.1. The load is to be applied on the pin (specimen) by dead weight through pulley string arrangement. The wear tests are performed as per standards of ASTM G-99 with the unlubricated condition in a normal laboratory atmosphere at 55% relative humidity and a temperature of 27-31°C. Each aluminium-red mud composite samples are conducted wear tests for 6 hours. The samples are cleaned with the solution of tetra chloro ethylene before and after the wear test.

Figure 5.1: Pin-on-disc wear testing machine

The wear rate tables for pure aluminium with 2%, 4% and 6% weight fractions of red mud with 200 rpm, 400 rpm and 600 rpm pin-on-disc speed at normal condition are placed in Appendix-II-A (i, ii, and iii). The experimental wear test results of aluminium-red mud metal matrix composites at normal condition are placed in Table 5.1. It has been observed that the better wear resistance is obtained for pure aluminium with 6% red mud of 42 nm particle size at 600 rpm. The higher percentage of nano particles provided with greater iron oxide (Fe_2O_3), SiO_2 and TiO_2 .

Table 5.1: Experimental wear test results of aluminum-red mud metal matrix composites at normal condition

S. No	Weight of red mud (%)	Particle size	Speed (RPM)	Wear rate $\times 10^{-6}$ N/m		
				At 10N load	At 20N load	At 30N load
1	0	45 μ m	200	0.691	1.012	1.331

38	6	42 nm	400	0.132	0.235	0.334
39	6	42 nm	600	0.122	0.229	0.332

The plot between wear rate and 2%, 4% and 6% weight fractions of red mud, for the particle size of 100 μm at 10N load is shown in Figure 5.2.

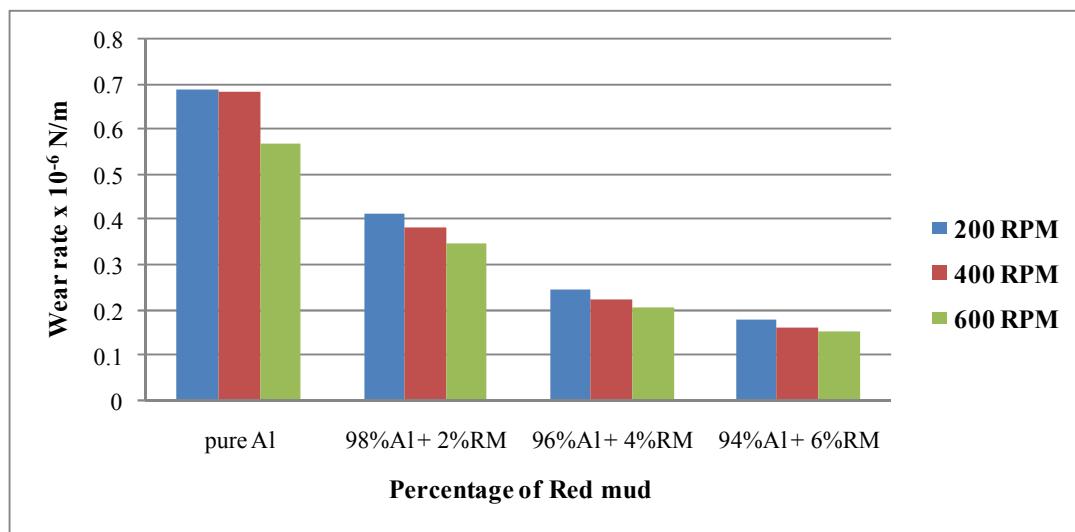

Figure 5.2: Plot between wear rate and percentage of red mud, for particle size of 100 μm of 10N load

The plot between wear rate and 2%, 4% and 6% weight fractions of red mud, for the particle size of 150 μm at 10N load is shown in Figure 5.3.

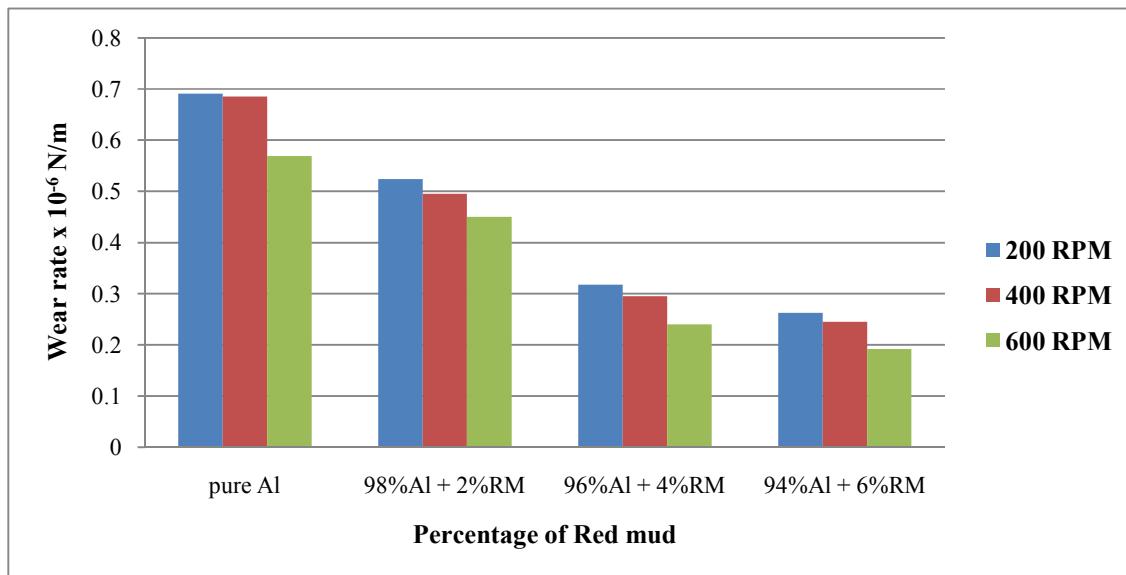

Figure 5.3: Plot between wear rate and percentage of red mud, for particle size of 150 μm of 10N load

The plot between wear rate and 2%, 4% and 6% weight fractions of red mud, for the particle size of 200 μm at 10N load is shown in Figure 5.4.

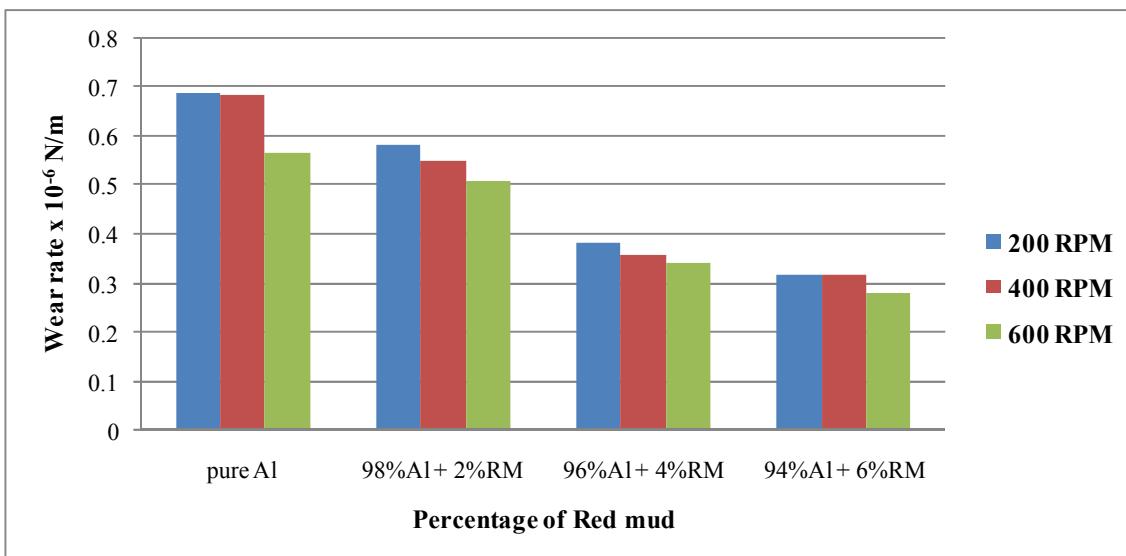

Figure 5.4: Plot between wear rate and percentage of red mud, for particle size of 200 μm of 10N load

The plot between wear rate and 2%, 4% and 6% weight fractions of red mud, for the particle size of 42 nm at 10N load is shown in Figure 5.5.

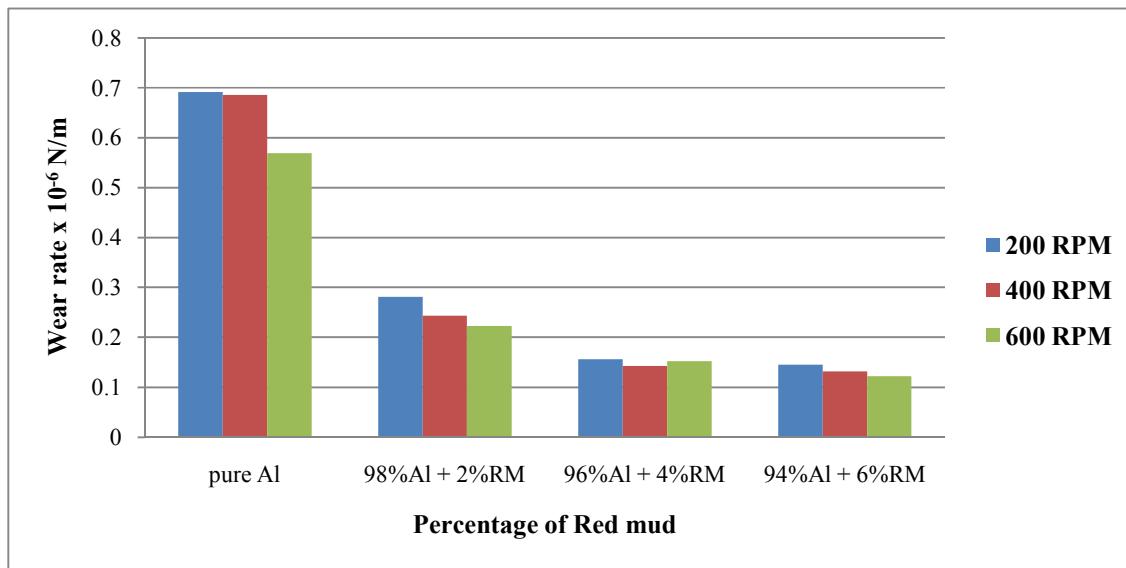

Figure 5.5: Plot between wear rate and percentage of red mud, for particle size of 42nm of 10N load

The plot between wear rate and 2%, 4% and 6% weight fractions of red mud, for the particle size of 100 μ m at 20N load is shown in Figure 5.6.

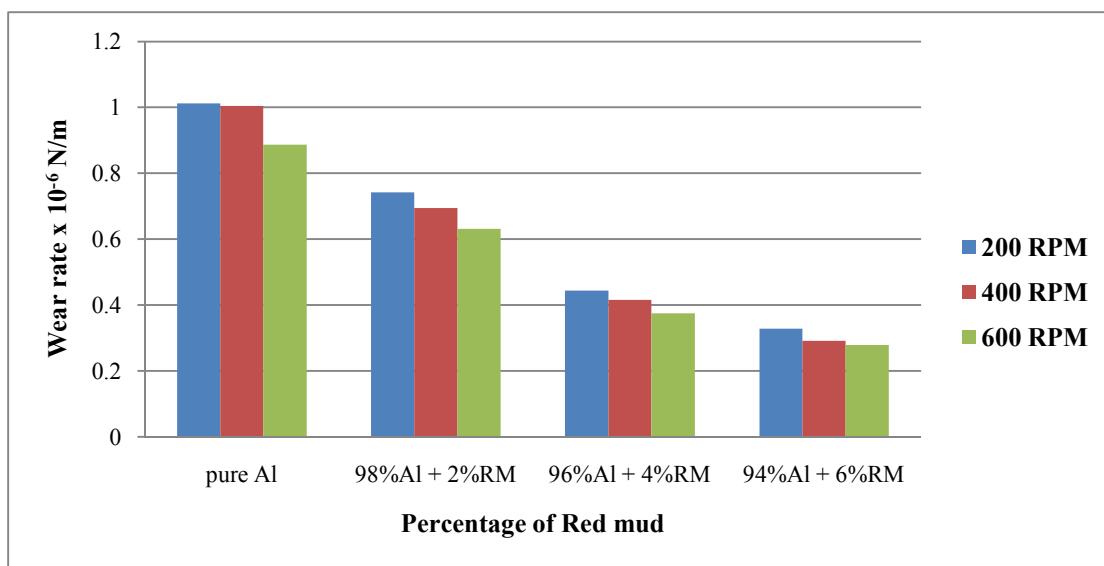

Figure 5.6: Plot between wear rate and percentage of red mud, for particle size of 100 μ m of 20N load

The plot between wear rate and 2%, 4% and 6% weight fractions of red mud, for the particle size of 150 μm at 20N load is shown in Figure 5.7.

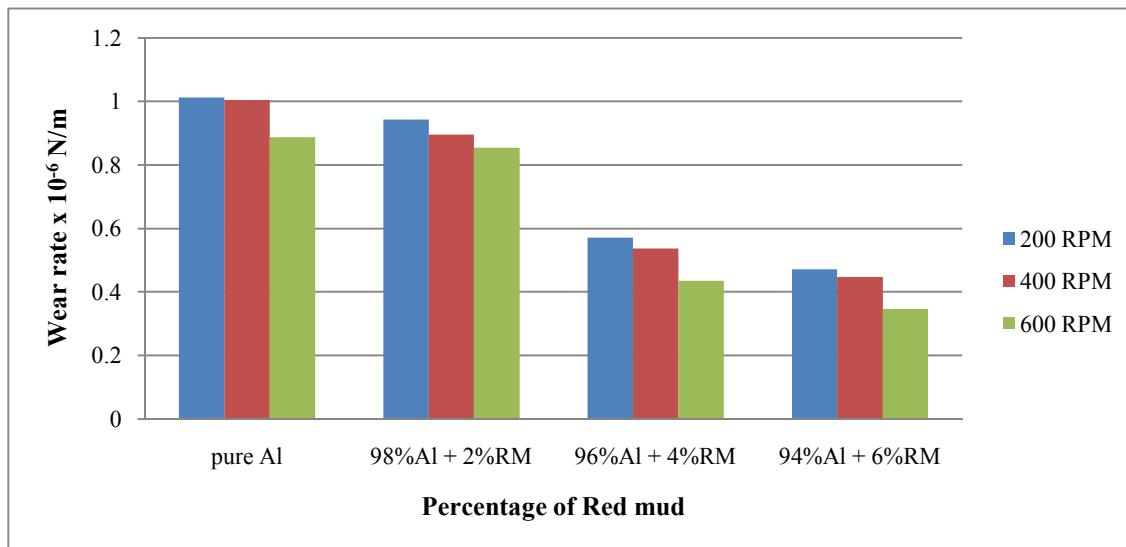

Figure 5.7: Plot between wear rate and percentage of red mud, for particle size of 150 μm of 20N load

The plot between wear rate and 2%, 4% and 6% weight fractions of red mud, for the particle size of 200 μm at 20N load is shown in Figure 5.8.

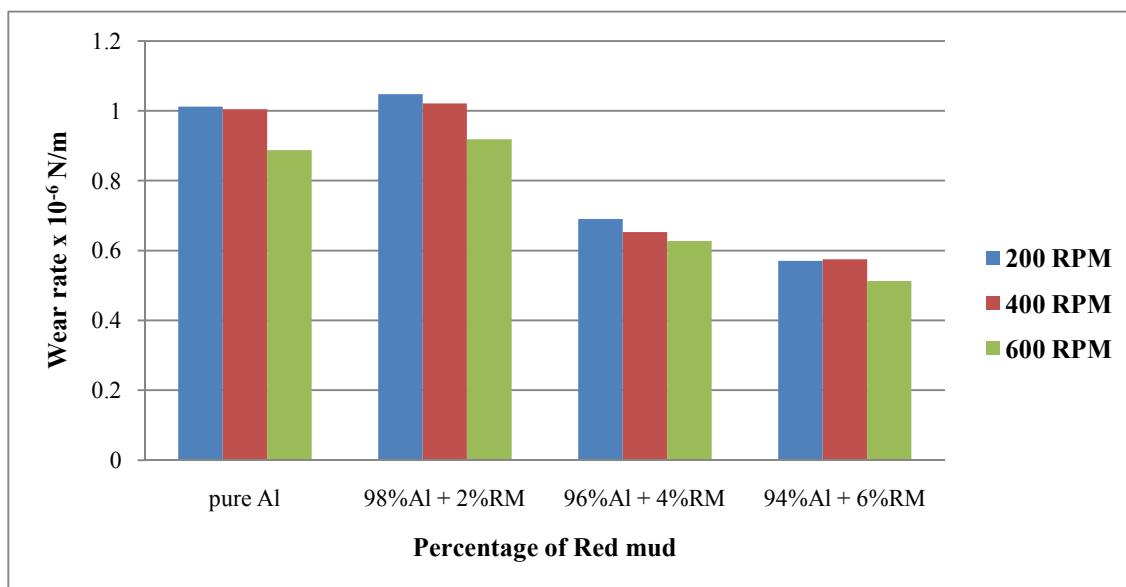

Figure 5.8: Plot between wear rate and percentage of red mud, for particle size of 200 μm of 20N load

The plot between wear rate and 2%, 4% and 6% weight fractions of red mud, for the particle size of 42nm at 20N load is shown in Figure 5.9.

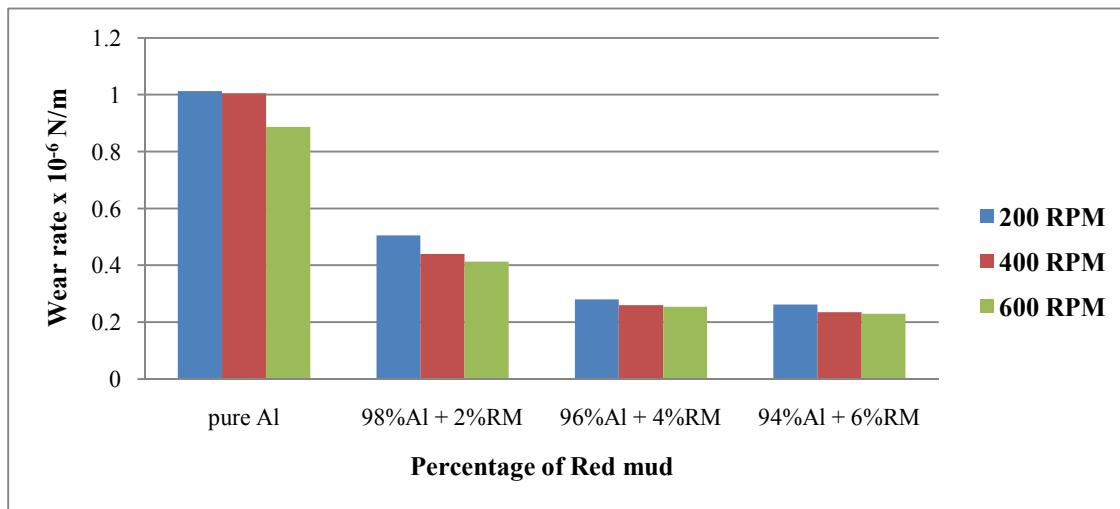

Figure 5.9: Plot between wear rate and percentage of red mud, for particle size of 42nm of 20N load

The plot between wear rate and 2%, 4% and 6% weight fractions of red mud, for the particle size of 100 μ m at 30N load is shown in Figure 5.10.

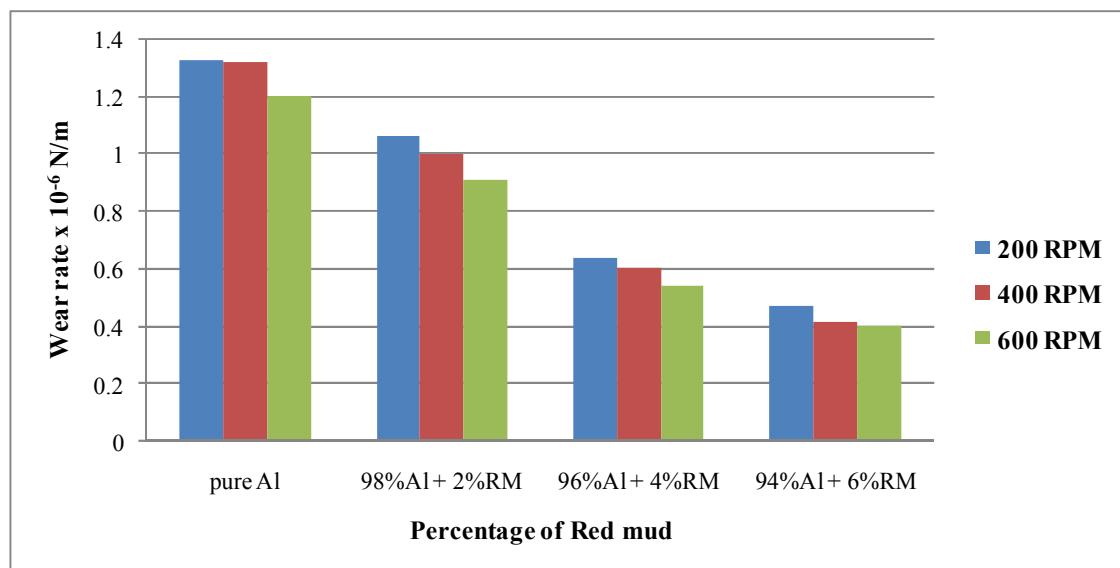

Figure 5.10: Plot between wear rate and percentage of red mud, for particle size of 100 μ m of 30N load

The plot between wear rate and 2%, 4% and 6% weight fractions of red mud, for the particle size of 150 μm at 30N load is shown in Figure 5.11.

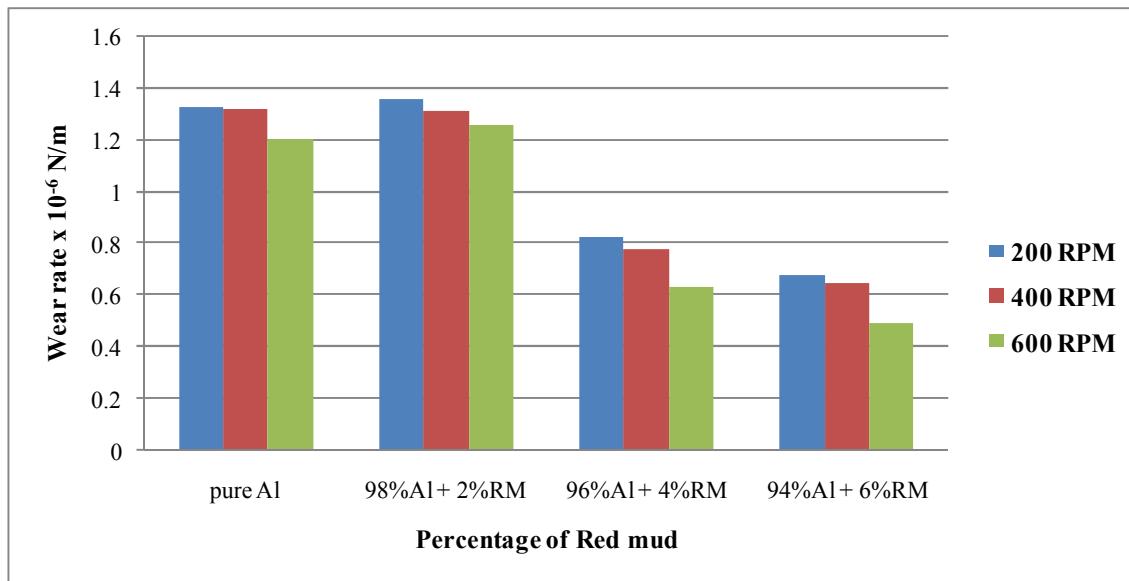

Figure 5.11: Plot between wear rate and percentage of red mud, for particle size of 150 μm of 30N load

The plot between wear rate and 2%, 4% and 6% weight fractions of red mud, for the particle size of 200 μm at 30N load is shown in Figure 5.12.

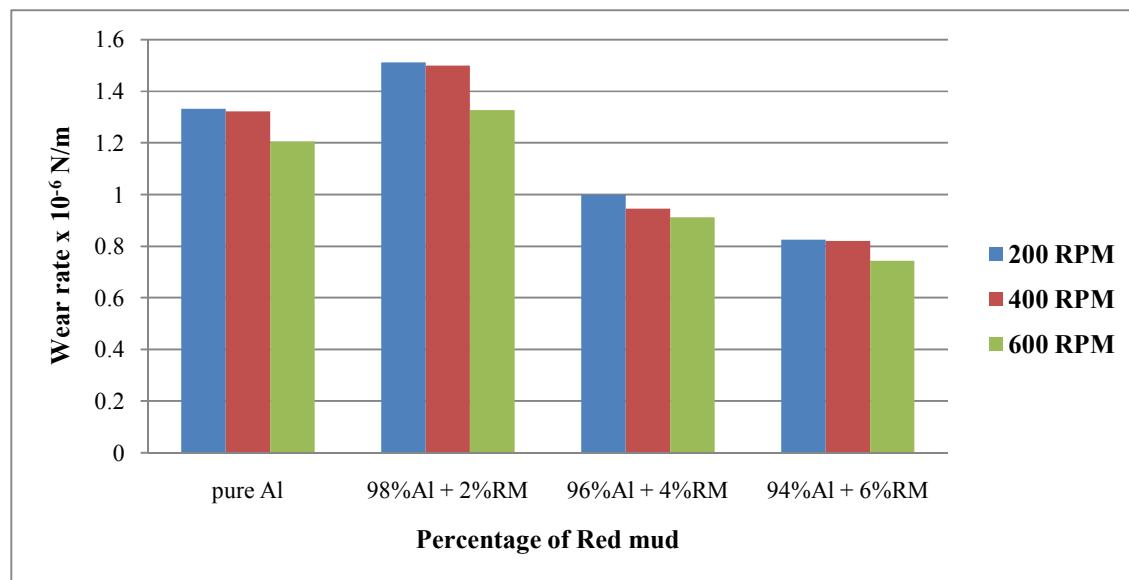

Figure 5.12: Plot between wear rate and percentage of red mud, for particle size of 200 μm of 30N load

The plot between wear rate and 2%, 4% and 6% weight fractions of red mud, for the particle size of 42 nm at 30N load is shown in Figure 5.13.

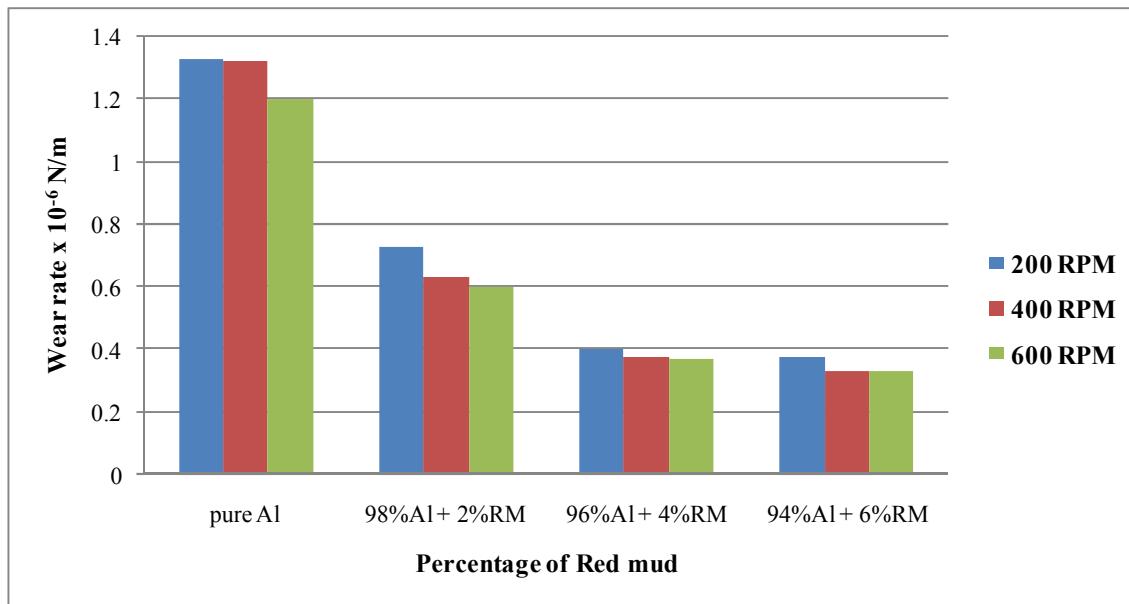

Figure 5.13: Plot between wear rate and percentage of red mud, for particle size of 42nm of 30N load

From Figure 5.2 to 5.13, it has been observed that the wear resistance is higher at 600 rpm speed compared to 400 rpm and 200 rpm speed. The 6% weight fraction of red mud with aluminium has better wear resistance because of the more iron oxide percentage value about 53.8% as a constituent element in red mud. As the increase in speed of rotation of the specimen, higher is the wear resistance. The Wear rate tables of 2%, 4% and 6% weight fractions of red mud, for the particle size of 100 μ m, 150 μ m, 200 μ m and 42 nm at 10N, 20N and 30N load are shown in Appendix-II-A (i, ii and iii).

5.3 WEAR CHARACTERISTICS ANALYSIS AT HEAT TREATMENT CONDITIONS

From Appendix-II-A (i, ii and iii), it is observed that red mud particle size of 100 μ m has better wear resistance among 100 μ m, 150 μ m and 200 μ m particle size of red mud with pure aluminium at normal condition. So, heat treatment is done for the particle size of 100 μ m (micron level) and 42 nm (nano level) red mud of 6% weight composition with pure aluminium at 350 $^{\circ}$ C, 400 $^{\circ}$ C, 450 $^{\circ}$ C and 500 $^{\circ}$ C (Air Cooling) conditions. The wear rate tests are performed at 200 rpm,

400 rpm, and 600 rpm for both micro and nano level red mud with pure aluminium metal matrix composites. The wear rate tables for pure aluminium with 2%, 4% and 6% weight fractions of red mud with 200 rpm, 400 rpm and 600 rpm pin-on-disc speed at heat treatment conditions are placed in Appendix-II-B (i, ii and iii).

5.3.1 Micro Level (100 μm)

The wear rate values for pure aluminium with 6% red mud of 100 μm particle size at 600 rpm and 450^0C temperature is shown in Table 5.2. The remaining 100 μm , 150 μm and 200 μm (2%, 4% and 6% weight fraction of red mud) at 200 rpm, 400 rpm and 600 rpm are shown in Appendix II:B.

It has been observed that the better wear resistance is obtained for pure aluminium with 6% red mud of 100 μm particle size (micro level) at 600 rpm speed. In the case of 100 μm , the wear resistance is improved up to 450^0C only and then wear resistance starts declining in nature.

5.3.2 Nano Level (42 nm)

The wear rate values for pure aluminium with 6% red mud of 42 nm particle size at 600 rpm and 450^0C temperature is shown in Table 5.2. The 42 nm particle size of 2%, 4% and 6% weight fraction of red mud at 200 rpm, 400 rpm and 600 rpm are shown in Appendix II:B. The wear rate values for pure aluminium with 6% red mud of 42 nm particle size at 600 rpm, at 450^0C temperature is shown in Table 5.2.

It has been observed that the better wear resistance is obtained for pure aluminium with 6% red mud of 42 nm particle size (nano level) at 600 rpm speed. In the case of 42 nm, the wear resistance is improved up to 450^0C only and then wear resistance starts declining in nature.

In Table 5.2, the experimental wear test results of heat treated aluminium-red mud metal matrix composite samples are shown at 10N, 20N and 30N load.

Table 5.2: Experimental wear test results of heat treated aluminum-red mud metal matrix composites

S.No.	Wt of Red mud (%)	Temperature (°C)	Particle Size	Speed (rpm)	Wear Rate x10 ⁻⁶ N/m		
					at 10 N load	at 20 N load	at 30 N load
1	6	350	100 µm	200	0.169	0.179	0.182

10	6	400	100 µm	600	0.120	0.127	0.136
11	6	450	100 µm	600	0.112	0.118	0.120
12	6	500	100 µm	600	0.118	0.125	0.128
13	6	350	42 nm	200	0.123	0.131	0.137
14	6	400	42 nm	200	0.118	0.125	0.132
15	6	450	42 nm	200	0.107	0.113	0.119
16	6	500	42 nm	200	0.115	0.122	0.126
17	6	350	42 nm	400	0.102	0.108	0.114
18	6	400	42 nm	400	0.095	0.101	0.105
19	6	450	42 nm	400	0.089	0.094	0.101
20	6	500	42 nm	400	0.091	0.096	0.105
21	6	350	42 nm	600	0.094	0.099	0.103
22	6	400	42 nm	600	0.085	0.090	0.095
23	6	450	42 nm	600	0.081	0.086	0.089
24	6	500	42 nm	600	0.083	0.088	0.092

The plot between wear rate, speed and temperature at 6% red mud of 100 µm particle size with pure aluminium at 10N, 20N and 30N load are shown in Figure 5.14, 5.15 and 5.16 respectively.

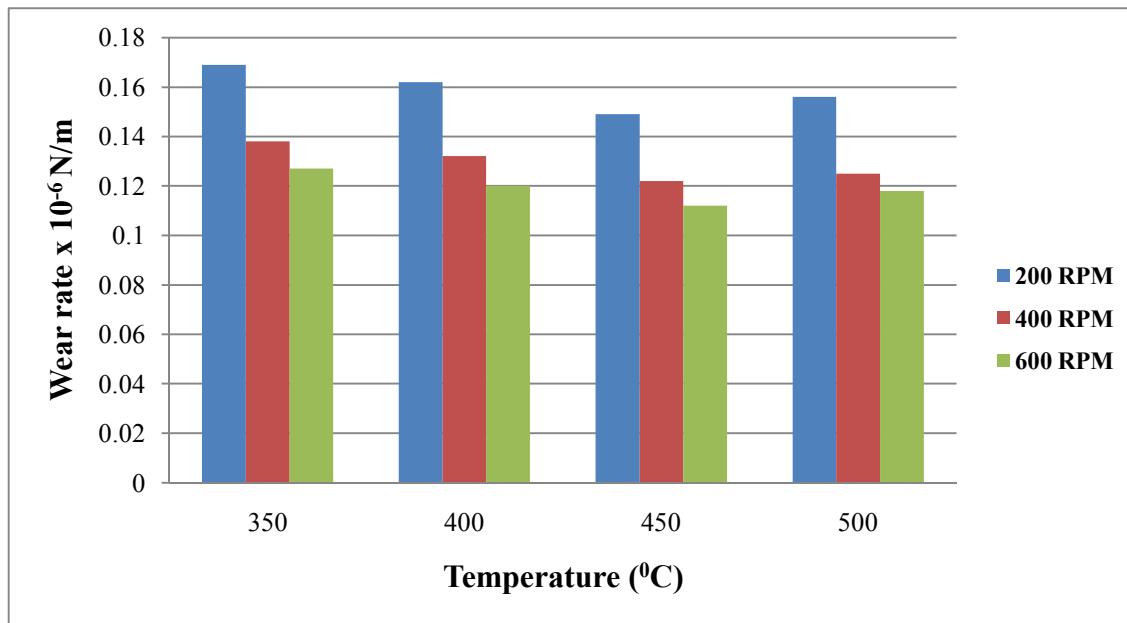

Figure 5.14: Wear rate, speed Vs temperature at 6% red mud (100 μm) with pure aluminium at 10N load

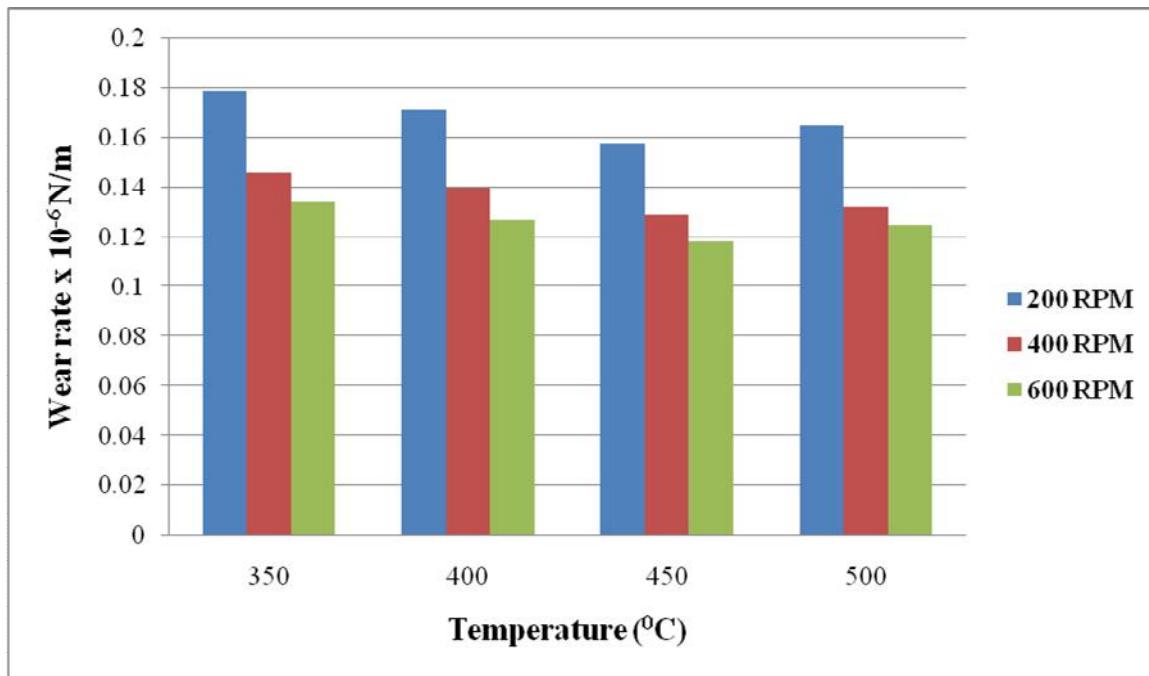

Figure 5.15: Wear rate, speed Vs temperature at 6% red mud (100 μm) with pure aluminium at 20N load

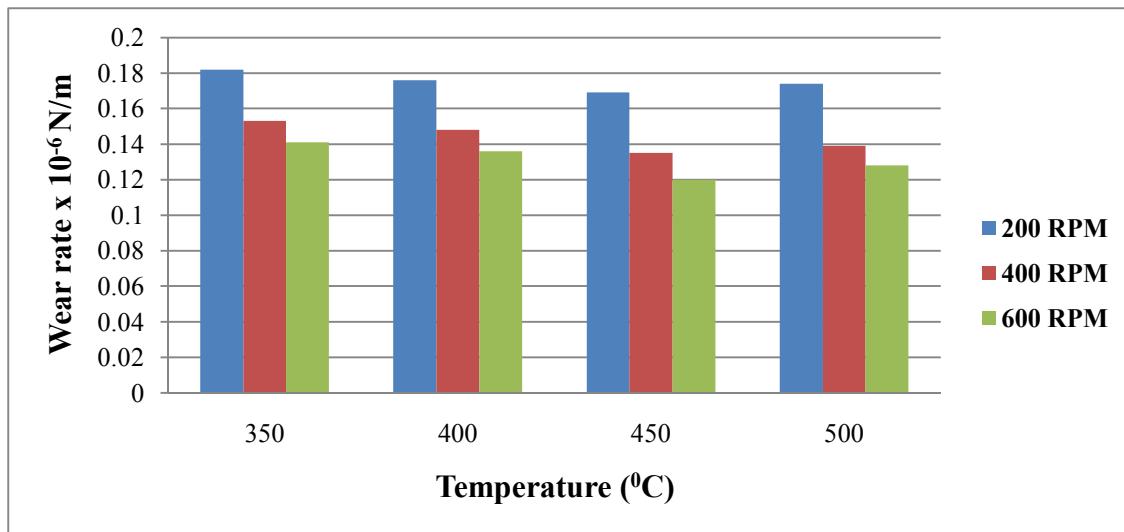

Figure 5.16: Wear rate, speed Vs temperature at 6% red mud (100 µm) with pure aluminium at 30N load

From Figure 5.14 -5.16, it has been observed that the specific wear rate decreases with increase in percentage weight fraction of red mud for 100 µm particle size at higher loads. Therefore, wear resistance is improved as co-efficient of friction decreases at higher loads.

The plot between wear rate, speed and temperature at 6% red mud of 42 nm particle size with pure aluminium at 10N, 20N and 30N load are shown in Figure 5.17, 5.18 and 5.19 respectively.

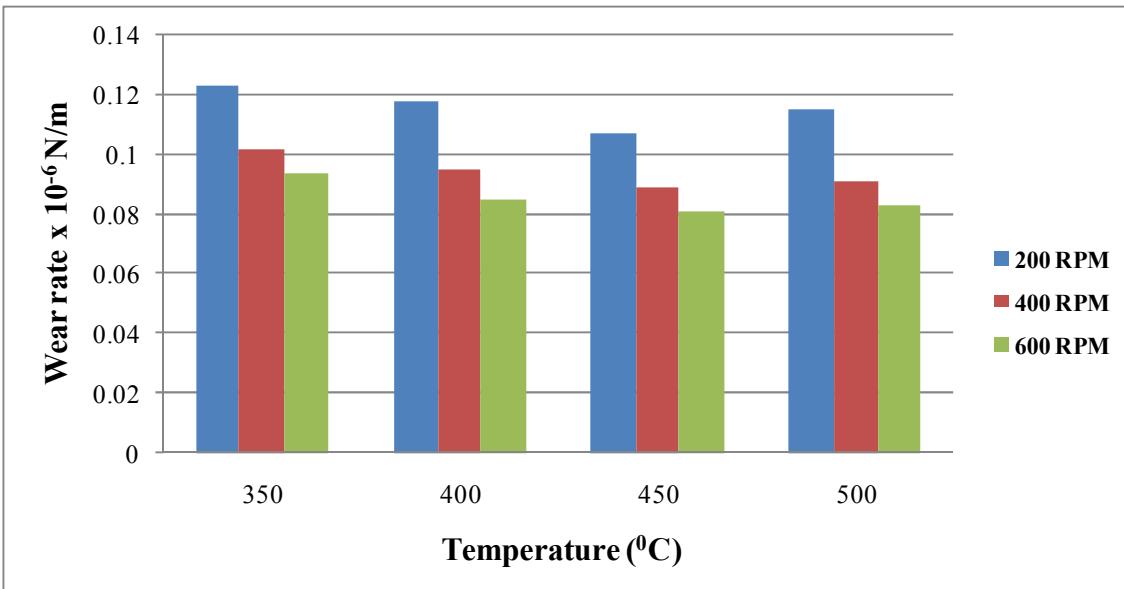

Figure 5.17: Wear rate, speed Vs temperature at 6% red mud (42 nm) with pure aluminium at 10N load

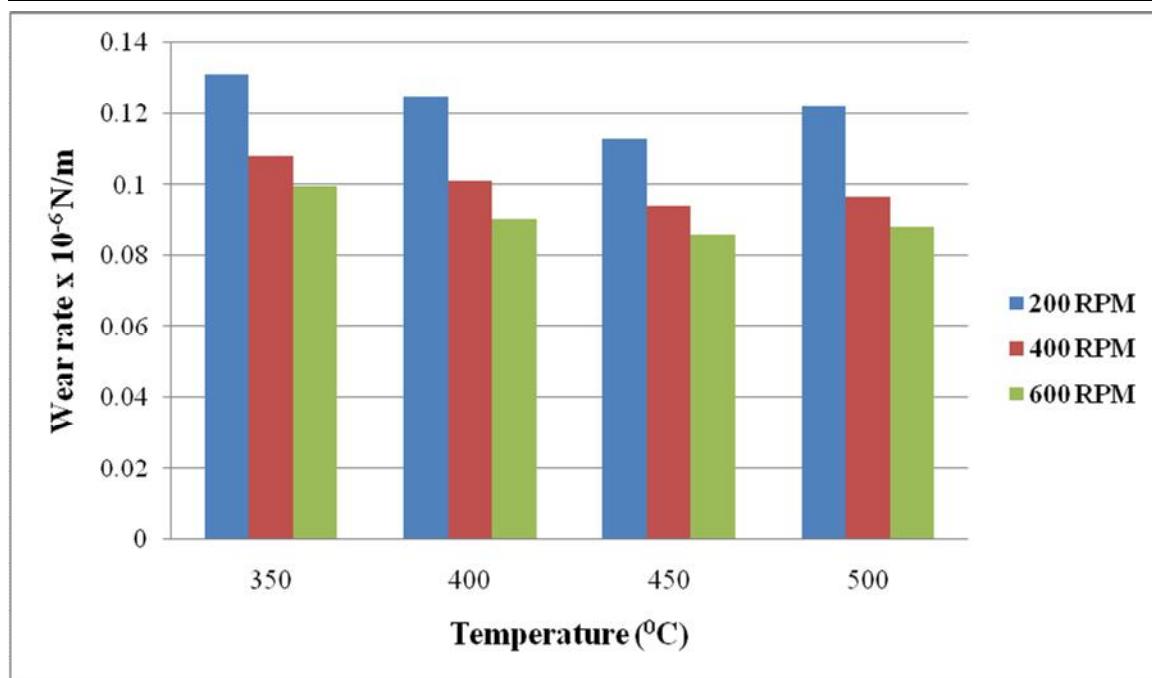

Figure 5.18: Wear rate, speed Vs temperature at 6% red mud (42 nm) with pure aluminium at 20N load

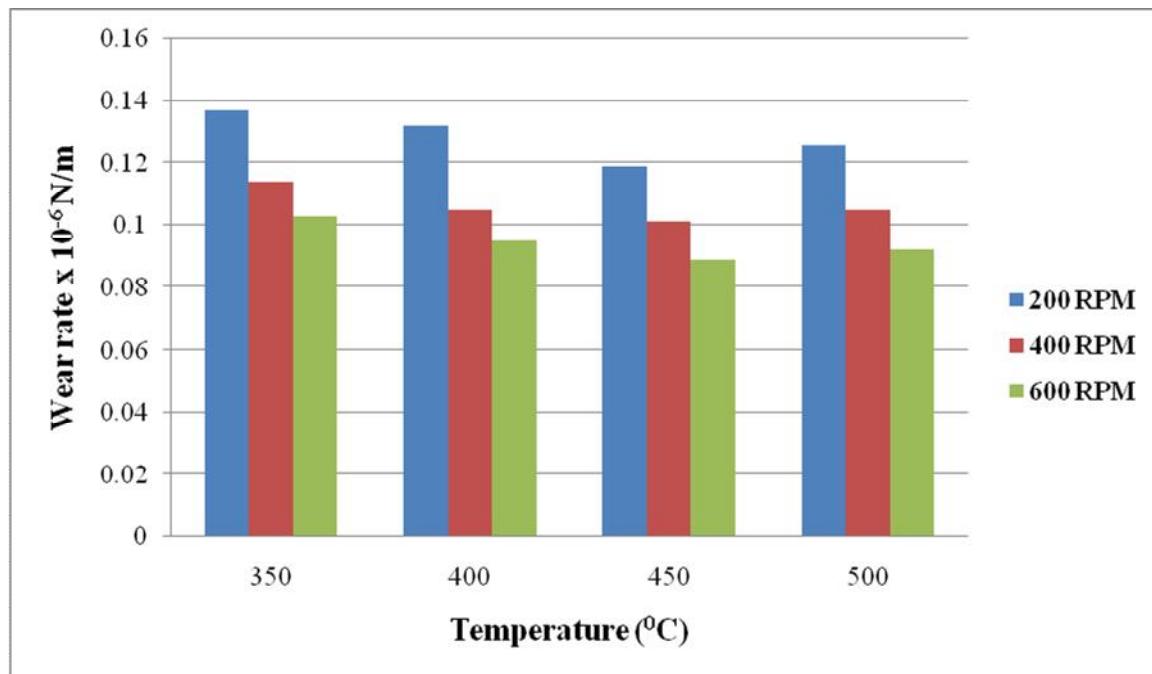

Figure 5.19: Wear rate, speed Vs temperature at 6% red mud (42 nm) with pure aluminium at 30N load

From Figure 5.17 -5.19, it has been observed that the specific wear rate decreases with increase in percentage weight fraction of red mud for 42 nm particle size at higher loads. Therefore, wear resistance is improved as co-efficient of friction decreases at higher loads.

5.4 MATHEMATICAL MODELING BY REGRESSION ANALYSIS

A mathematical model is developed for pure aluminium and red mud at normal condition and the overall equation is obtained using Regression analysis which is shown in equation 5.1.

$$\text{Wear rate} = 0.434552 + [(0.001107) \times \text{particle size}] - [(0.0519) \times \text{percentage Weight fraction of red mud}] - [(0.00013) \times \text{speed}] \quad (5.1)$$

As per the developed regression statistics, the R square value is 0.912814 and obtained standard error is 0.03928.

A $100 \mu\text{m}$ model is developed for pure aluminium and red mud at heat treatment condition and the overall equation is obtained using Regression analysis which is shown in equation 5.2.

$$\text{Wear rate} = 0.168434 - [(8.2 \times 10^{-5}) \times \text{Temperature}] + [(0.000373) \times \text{particle size}] - [(8.7 \times 10^{-5}) \times (\text{speed})] \quad (5.2)$$

Figure 5.20: Regression statistics of Wear rate results for pure aluminium and red mud at heat treatment condition

The regression statistics for pure aluminium and red mud metal matrix composites at heat treatment condition is shown in Figure 5.20. It is observed that the R-square value is 0.9461 and adjusted R-square value is 0.9381. As per the regression statistics, the influence of red mud particle size has much higher than temperature and speed properties.

5.5 RESULTS

- The red mud constituents (Ferrous oxide) are harder in nature, as the percentage weight fraction of the red mud increases, the wear resistance of the whole composite also increases. The maximum wear resistance is obtained for 42 nm level of 6% weight fraction of red mud with pure aluminium compared to 100 μm level of red mud reinforced aluminium metal matrix composites.
- The dispersion of oxide phases like Fe_2O_3 , Al_2O_3 and TiO_2 etc., might have uniformly presented throughout the pure aluminium matrix which strengthened the metal matrix composite material.
- As the increase in speed of rotation of the specimen, the wear rate is decreased which means that wear resistance is higher. Highest wear resistance is observed for the test specimen with 42 nm size and 6% weight fraction of red mud with pure aluminium at 600 RPM speed.
- As particle size decreases, there is a significant improvement in wear resistance. As compared to micro level, nano level has achieved the highest wear resistance also due to the interfacial area between the matrix material aluminium and reinforced material red mud. In both the cases of 100 μm and 42 nm, up to 450^0C only the wear resistances is improved and then wear resistance starts declining in nature.

5.6 SUMMARY

The present chapter gives the results of tribological characterization such as wear rate at normal condition and heat treatment conditions of pure aluminium with red mud metal matrix composites. The graphs are plotted for micro and nano level combinations of red mud with pure aluminium metal matrix composites. The chapter also presents mathematical modeling using regression analysis.

CHAPTER-6

TRIBOLOGICAL CHARACTERIZATION OF PURE ALUMINIUM WITH RED MUD AND TUNGSTEN CARBIDE

6.1 INTRODUCTION

The present chapter is describing the tribological characterization of aluminium with red mud and tungsten carbide metal matrix hybrid composites at normal and heat treatment conditions. The wear characteristics are investigated with an optimal combination of aluminium with 4% tungsten carbide and 2%, 4% and 6% weight fractions of micro and nano level red mud metal matrix composites. Using regression analysis, the mathematical prediction is carried out for both normal and heat treatment conditions.

6.2 WEAR CHARACTERISTICS ANALYSIS AT NORMAL CONDITION

The pin-on-disc wear testing machine conditions are specified in section 5.2 in chapter 5. All the wear tests were carried out as per ASTM G-99 standard under unlubricated condition in a normal laboratory atmosphere at 50-60% relative humidity and a temperature of 28-32°C. The mass loss in the specimen after each test was estimated by measuring the weight of the specimen before and after each test using an electronic weighing machine having accuracy up to 0.01mg. Care has been taken so that the specimens under test are continuously cleaned with a woolen cloth to avoid the entrapment of wear debris and to achieve uniformity in the experimental procedure. The test pieces are cleaned with a tetra-chloro-ethylene solution prior and after each test.

The wear rate results for aluminium- red mud-tungsten carbide metal matrix composites at normal condition are shown in Table 6.1. The graph between wear rate and % weight fraction of red mud and 4% tungsten carbide with pure aluminium at normal condition is shown in Figure 6.1.

Table 6.1: Wear rate results for aluminium-red mud-tungsten carbide metal matrix composites at normal condition

Aluminium and 4% WC with % weight fraction of Red mud(RM)	Particle size	Wear rate x 10 ⁻⁶ (N/m)		
		at 10 N	at 20 N	at 30 N
Al+4% WC +2% RM	100 µm	0.346	0.618	0.887
Al+4% WC + 4% RM	100 µm	0.201	0.355	0.507

Al+4% WC +6% RM	42 nm	0.119	0.227	0.334

The plots between wear rate and percentage weight fractions of red mud, for the particle size of 100 μ m, 150 μ m, 200 μ m and 42 nm at 10N, 20N and 30N load are shown in Figure 6.1 to 6.3.

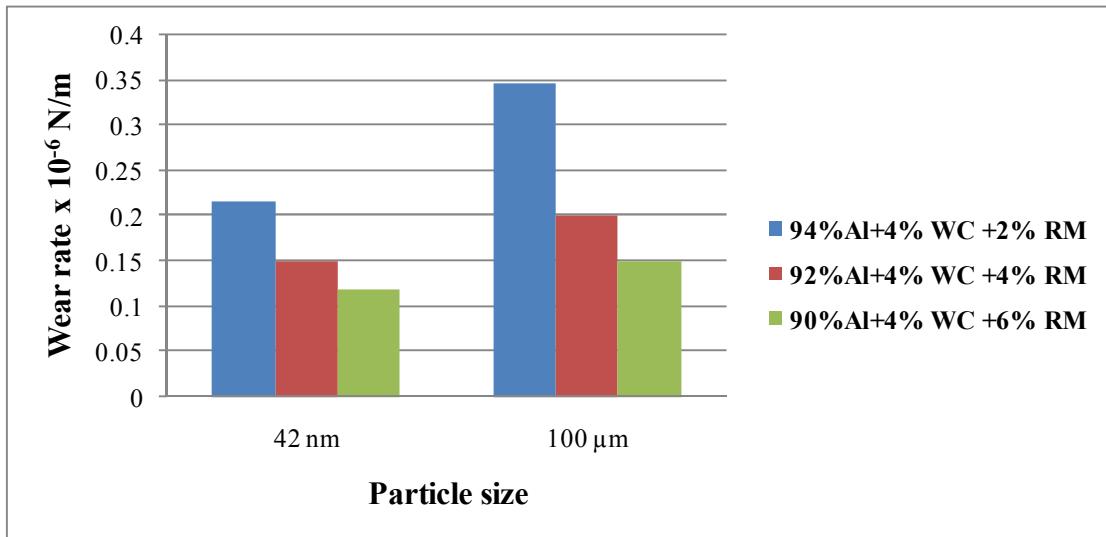

Figure 6.1: Plot between wear rate and particle size of Al+%WC+%RM for 10N load at normal condition

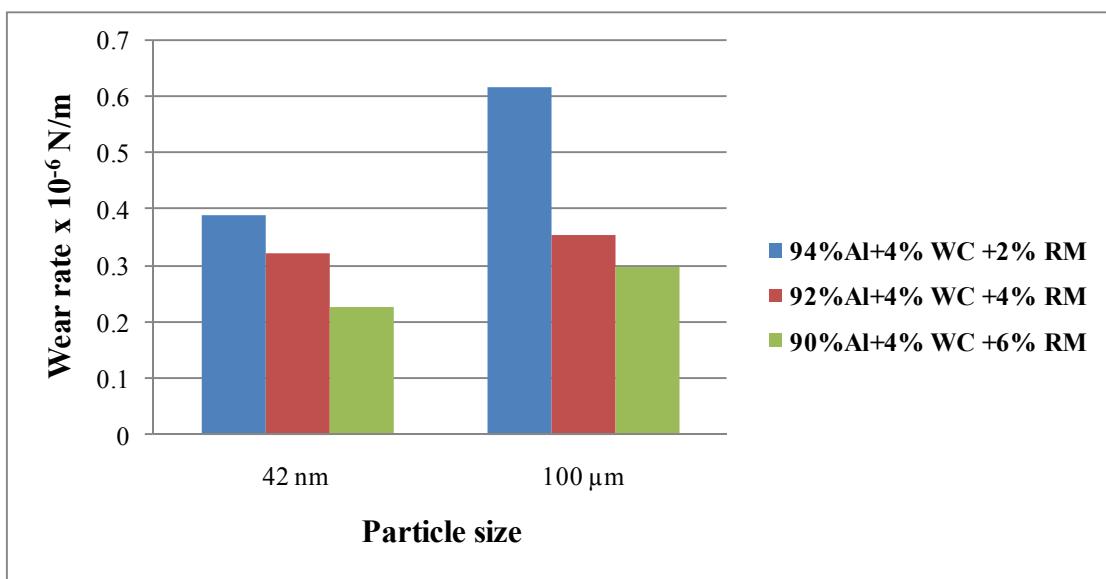

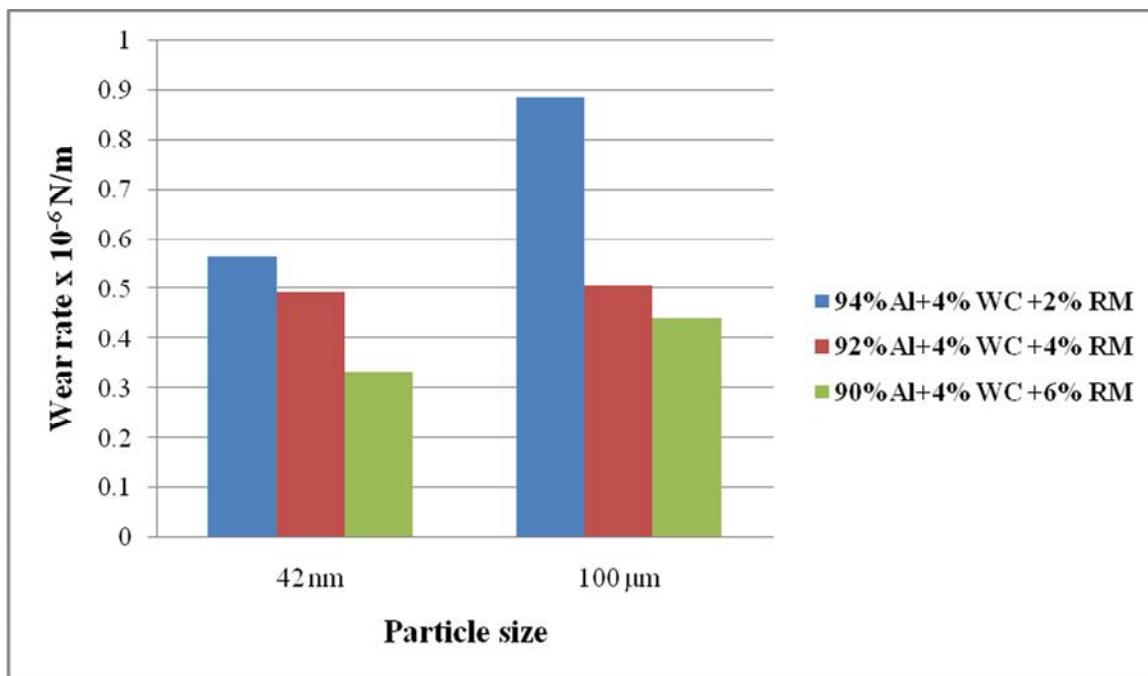

Figure 6.2: Plot between wear rate and particle size of Al+%WC+%RM for 20N load at normal condition

**Figure 6.3: Plot between wear rate and particle size of Al+%WC+%RM for 30N load
at normal condition**

It is observed that for the same percentage weight fraction of red mud, the wear rate is higher for the micro level reinforcement than nano level reinforcement from Figure 6.1 - 6.3. Therefore, wear resistance is more for nano level 6% weight fraction of red mud with 90% aluminium and 4% tungsten carbide metal matrix hybrid composite. The wear rate tables for pure aluminium with red mud and tungsten carbide at normal condition are placed in Appendix III: A (i, ii, and iii).

6.3 WEAR CHARACTERISTICS ANALYSIS AT HEAT TREATMENT CONDITIONS

In Table 6.2, the experimental wear test results of heat treated aluminium-red mud-tungsten carbide metal matrix hybrid composites are shown at 10N, 20N and 30N load. The plot between wear rate, % weight fraction of red mud and temperature of 100 μ m particle size with pure aluminium and 4% tungsten carbide at 10N, 20N and 30N loads are shown in Figure 6.4, 6.5 and 6.6 respectively. The wear rate tables for pure aluminium with red mud and tungsten carbide at heat treatment conditions are placed in Appendix III: B (i, ii, and iii).

Table 6.2: Experimental wear test results of heat treated aluminium - red mud – tungsten carbide metal matrix hybrid composites

S.No	Weight of red mud (%)	Weight of Tungsten Carbide (%)	Particle size (Microns)	Heat treatment Temperature (°C)	Wear rate $\times 10^{-6} \text{N/m}$		
					At 10N load	At 20N load	At 30N load

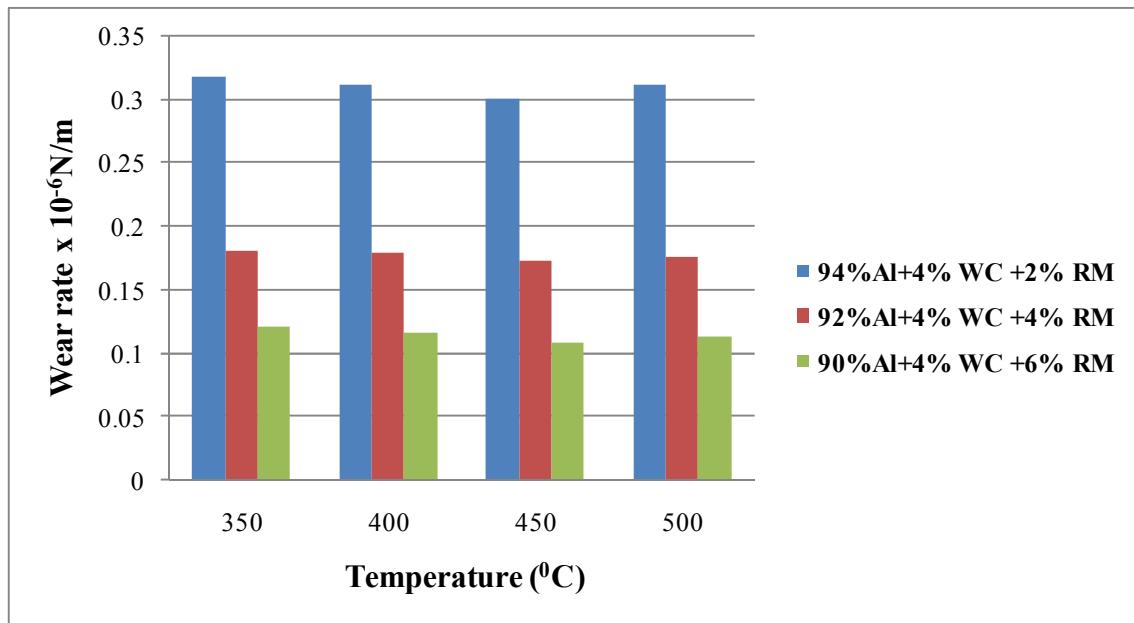

Figure 6.4: Wear rate, % weight fraction of red mud (100 μm) with aluminium and tungsten carbide and temperature at 10N load

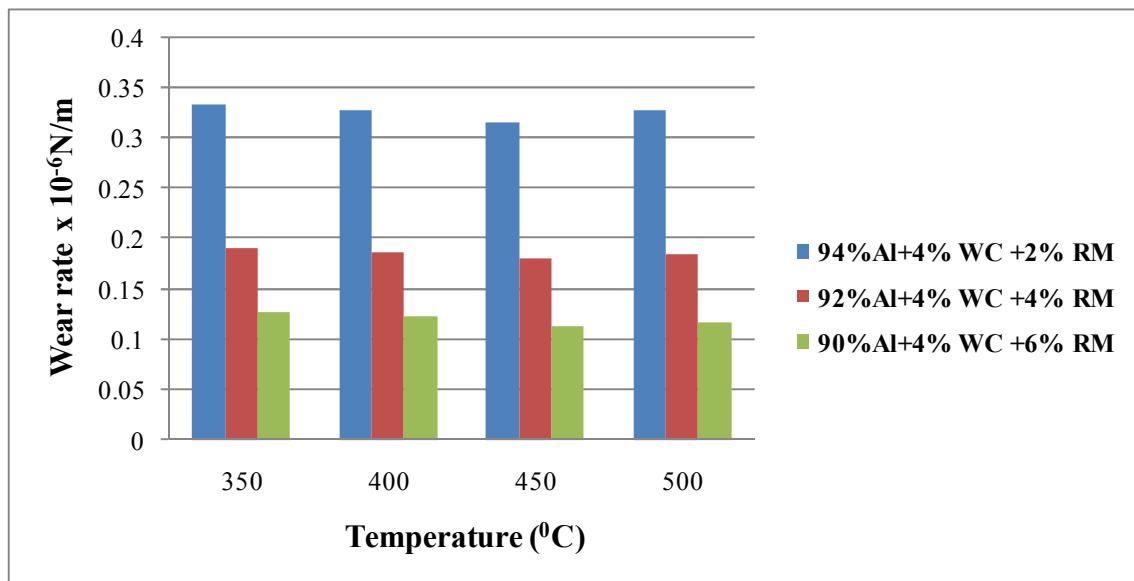

Figure 6.5: Wear rate and % weight fraction of red mud (100 μm) with aluminium and tungsten carbide and temperature at 20N load

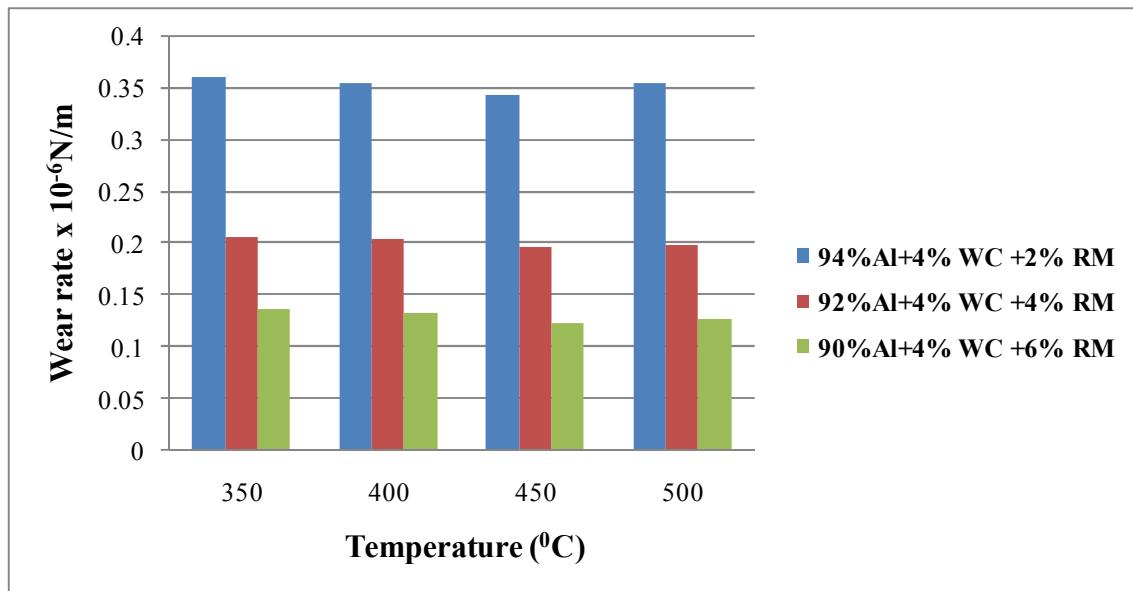

Figure 6.6: Wear rate and % weight fraction of red mud (100 µm) with aluminium and tungsten carbide and temperature at 30N load

The plot between wear rate, % weight fraction of red mud and temperature of 42 nm particle size with pure aluminium and 4% tungsten carbide at 10N, 20N and 30N loads are shown in Figure 6.7, 6.8 and 6.9 respectively.

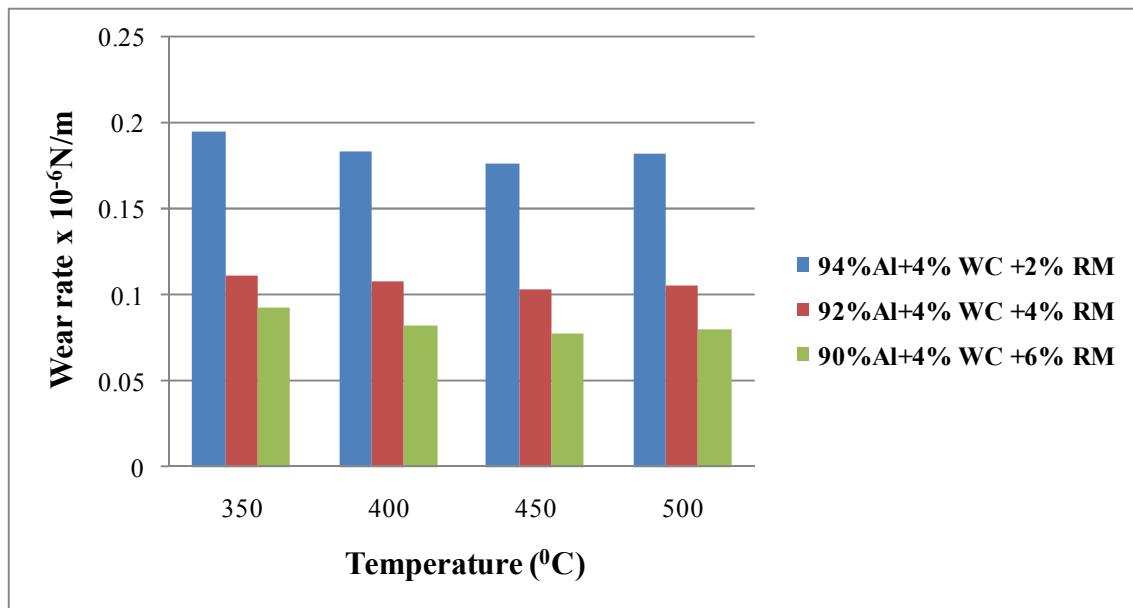

Figure 6.7: Wear rate, % weight fraction of red mud (42 nm) with aluminium and tungsten carbide and temperature at 10N load

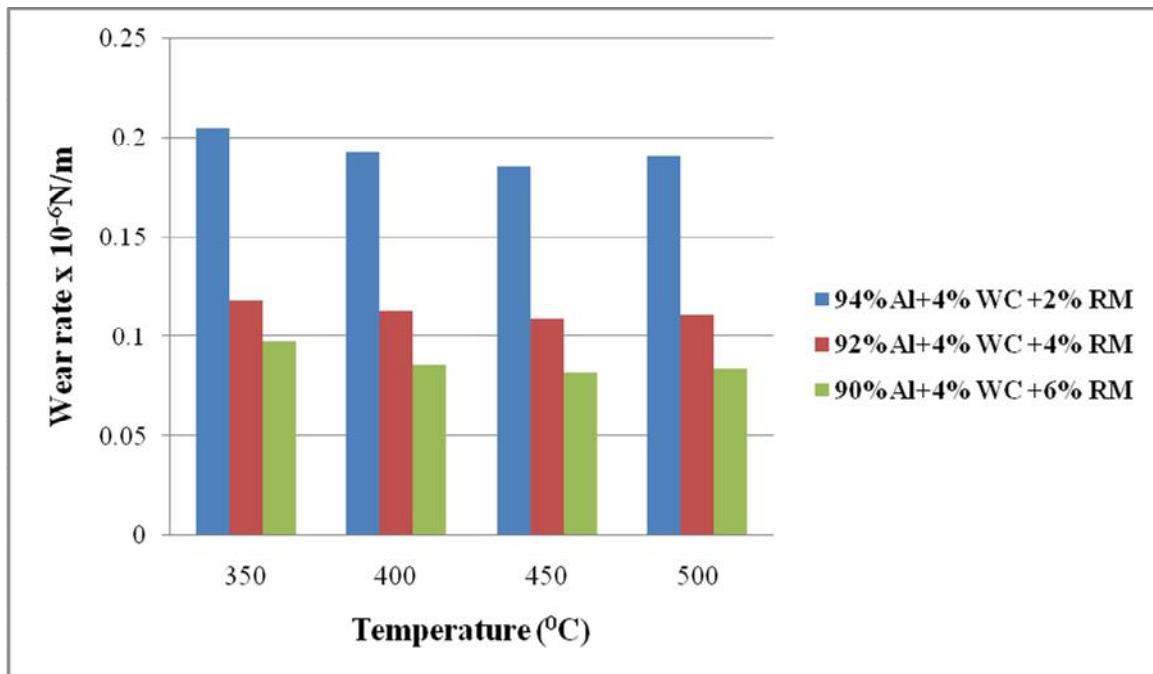

Figure 6.8: Wear rate and % weight fraction of red mud (42 nm) with aluminium and tungsten carbide and temperature at 20N load

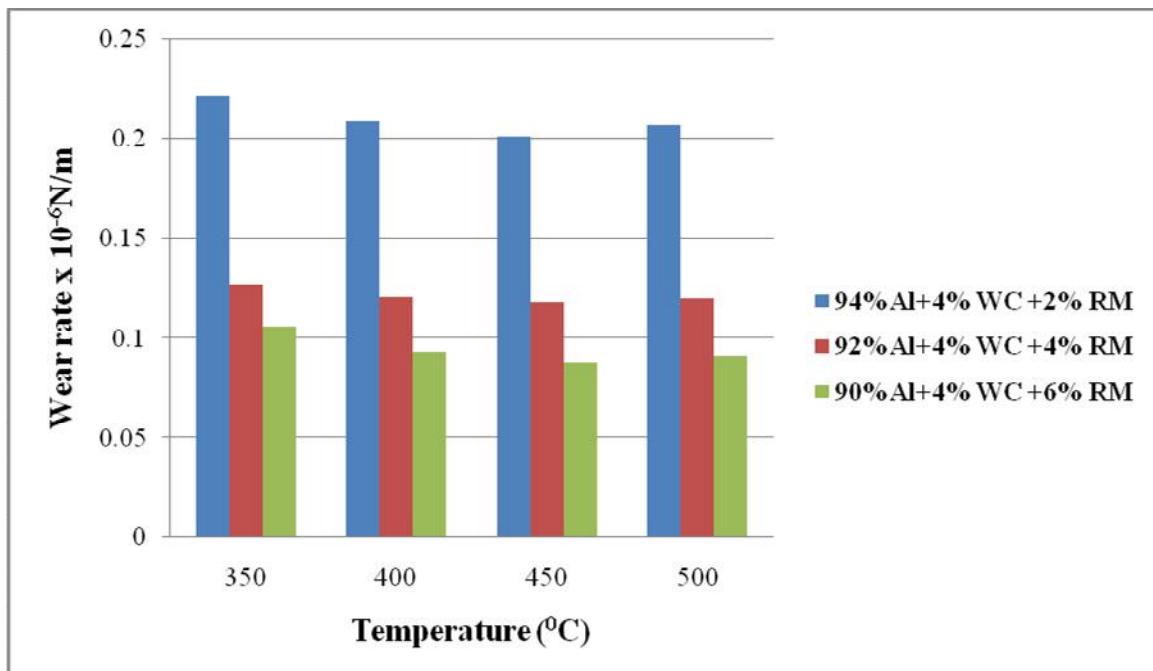

Figure 6.9: Wear rate and % weight fraction of red mud (42 nm) with aluminium and tungsten carbide and temperature at 30N load

The wear rate tables for pure aluminium with red mud and tungsten carbide at heat treatment conditions are placed in Appendix III: B. From Figure 6.7 – 6.9, it is observed that the wear resistance values are improved up to 450°C, after that there is a decrement in wear resistance values. In heat treatment conditions, wear resistance values are higher for the nano level reinforcement than micro level reinforcement compared to normal condition. This is owing to the increase in surface area of contact and higher bond strengths.

6.4 MATHEMATICAL MODELING BY REGRESSION ANALYSIS

A mathematical model is developed for aluminium, red mud and tungsten carbide at normal condition and the overall equation is obtained using Regression analysis which is shown in equation 6.1. The R-square value 0.8757 is obtained from regression statistics.

$$\text{Wear Rate} = 0.3079739 - \text{Wt\% Red mud (0.0365)} + \text{Particle size (0.00070693)} \dots \dots \dots \quad (6.1)$$

A mathematical model is developed for aluminium, red mud and tungsten carbide at heat treatment condition and the overall equation is obtained using Regression analysis which is shown in equation 6.2.

$$\begin{aligned} \text{Wear Rate} = & 0.3278566 - [\text{Temperature in } ^\circ\text{C} \times (0.000153666)] + [\text{Particle size} \times (0.00083451)] \\ & - [\% \text{ weight composition of red mud} \times (0.034)] \dots \dots \dots \quad (6.2) \end{aligned}$$

The regression statistics for pure aluminium and red mud metal matrix composites at heat treatment condition is shown in Figure 6.10. It is observed that the R-square value is 0.8643 and adjusted R-square value is 0.7940. As per the regression statistics in Figure 6.10, the influence of red mud particle size has much higher than temperature and speed properties.

Figure 6.10: Regression statistics for pure aluminium, red mud and tungsten carbide at heat treatment condition

6.5 RESULTS

- As % weight composition of red mud with pure aluminium and tungsten carbide increases, there is an improvement in wear resistance.
- The maximum wear resistance is obtained for 42 nm or 0.042 microns level of 6% weight fraction of red mud with pure aluminium and tungsten carbide.
- It is also observed that, for the same weight fraction of red mud compacted with pure aluminium and tungsten carbide, the wear resistance is higher for the nano structured reinforcement than micro structured reinforcement. This is owing to the increase in surface area of contact and higher bond strengths.
- As the increase in speed of rotation of the specimen, the wear resistance is increased. The highest wear resistance is observed for the test specimen with 42 nm size and 6% weight fraction of red mud powder at 600 RPM speed.
- A decrease in wear rate is observed with increase in the amount of temperature up to 450°C and then it is started for declining in nature.

6.6 SUMMARY

The present chapter gives the results of tribological characterization such as wear rate at normal condition and heat treatment conditions of pure aluminium with red mud and tungsten carbide metal matrix hybrid composites. The graphs are plotted for micro and nano level combinations of red mud and tungsten carbide with pure aluminium metal matrix hybrid composites. The chapter also presents mathematical modeling using regression analysis.

CHAPTER-7

CONCLUSIONS

7.1 CONCLUSIONS

The present work is focussed on the mechanical and wear behaviour of aluminium metal matrix composite reinforced with micro and nano red mud and tungsten carbide particles fabricated through powder metallurgy route. The influence of heat treatment on aluminium-red mud and aluminium-red mud-tungsten carbide metal matrix hybrid micro as well as nano composites at normal condition and heat treatment conditions have been reported. The prediction of hardness and wear behaviour of aluminium with micro and nano particulates of red mud and tungsten carbide at normal and heat treatment conditions using regression analysis.

The investigation is mainly to find the best weight fraction of red mud and tungsten carbide particulates as reinforced the aluminium metal matrix hybrid composites for optimum properties. Red mud is abundantly available in India. Such materials at micro/nano particulates can be used to develop aluminium hybrid composites at lower price, which are strong, hard and high wear resistance compared to base aluminium and such hybrid metal matrix composites can be used in place of aluminium.

The maximum hardness values at normal condition and heat treatment condition of 450^0C at 6% weight fraction of red mud are shown in Table 7.1 and 7.2 respectively. Aluminium metal matrix composite of (94%Al+6%RM) with 100 micron particulates has 74.50 VHN where as with 42 nano particulates has 75.23 VHN at normal condition. Aluminium metal matrix hybrid composite of (90%Al+4%WC+6%RM) with 100 micron particulates has 83.90 VHN where as with 42 nano particulates has 84.91 VHN at normal condition.

Table 7.1: Maximum hardness values at normal condition

Particle Size	Hardness (VHN) for 94%Al+6%RM	Hardness (VHN) for 90%Al+4%WC+6%RM
100 μm	74.50	83.90
42 nm	75.23	84.91

Aluminium metal matrix composite of (94%Al+6%RM) with 100 micron particulates has 82.4 VHN where as with 42 nano particulates has 84.2 VHN at heat treatment condition. Aluminium metal matrix hybrid composite of (90%Al+4%WC+6%RM) with 100 micron particulates has 95.7 VHN where as with 42 nano particulates has 96.8 VHN at heat treatment condition.

Table 7.2: Maximum hardness values at heat treatment condition of 450°C

Particle Size	Hardness (VHN) for 94%Al+6%RM	Hardness (VHN) for 90%Al+4%WC+6%RM
100 μm	82.4	95.7
42 nm	84.2	96.8

The following conclusions have been observed and drawn from this work.

- The particulate size of red mud is reduced from 400 nm to 42 nm after 30 hours of ball milling. Decreasing size of reinforced particle increases its surface to volume ratio tremendously. This is further exploited in the preparation of nano composites.
- The author has observed that the properties of aluminium based nano composites prepared by powder metallurgy route are better than the composites prepared by stir casting method. Naresh Prasad et al, 2013 presented the hardness of aluminium-red mud with 10% weight fraction of red mud is 52.78 VHN by stir casting method, where as the author developed same composite i.e aluminium-red mud with 6% weight fraction of red mud is 74.5 VHN. An improvement of 22% in hardness is achieved by composites prepared by powder metallurgy route compared to stir casting method.
- It is also observed that for the 6% weight fraction of red mud, the hardness and compression strength are higher for the nano structured reinforcement than micro structured reinforcement. The hardness is higher for 94%Al+6%RM of about 75.23 VHN at the nano level.

- Aluminium, red mud and tungsten carbide hybrid metal matrix composite is having more hardness compared to aluminium with red mud metal matrix composite. The hardness for 90%Al+4%WC+6%RM metal matrix hybrid composite is 95.7 VHN at micro level and 96.8 VHN at nano level of red mud. This is due to the presence of iron oxide in red mud and tungsten carbide.
- Hardness and compression strength properties are improved for nano level aluminium-red mud test specimen with 42 nm size and 6% weight fraction of Red mud. The simulated results of compression strength using Deform-2D software and experimental values are within the limits of 1-8% difference i.e., the % error is varied from 0.40 - 7.98.
- In heat treatment conditions, hardness values are higher for the nano structured reinforcement than micro structured reinforcement compared to normal condition. This is owing to the increase in surface area of contact and higher bond strengths. Under the highest load applied, the mating material raised the specimen temperature could cause oxidation of contact surfaces. The oxide films were brittle and easily smashed in the wear process. These oxide debris were embedded in the specimen surface by the contact load which enhanced its bond strength, hardness and increased its wear resistance. This is so called glazed hardening.
- As percentage weight fraction of red mud increases from 2%, 4% and 6%, better wear resistance is obtained at 6% red mud with 30N load on pin-on-disc wear testing machine.
- Highest wear resistance is observed for the test specimen with 42 nm particle size and 6% weight fraction of red mud with pure aluminium at 600 rpm speed and 30N load. The 6% weight fraction of nano red mud possessed more Fe_2O_3 . So, the test coupons exhibited a reduced wear rate at 600rpm because of iron oxide compared with 200 and 400 rpm. The higher percentage of nano particles provided with greater iron oxide (Fe_2O_3), SiO_2 and TiO_2 .
- The increase in bulk temperatures of the rubbing bodies decreases the flow stresses of the rubbing materials to a certain extent, which results in an increased in plastic zone size in the sub surfaces of the rubbing bodies, consequently the friction co-efficient as well as wear rate increases as the load on pin-on-disc wear testing machine increases.

- The predicted mathematical modeling results of wear rate using regression analysis and experimental values are within the limits of 1-4% error difference of pure aluminium-red mud metal matrix composites and pure aluminium-red mud-tungsten carbide hybrid metal matrix composites.
- Highest wear resistance is observed for the test specimen with 42 nm particle size and 6% weight fraction of red mud with pure aluminium and 4% tungsten carbide at 600 rpm speed.
- The chemical compatibility is excellent between pure aluminium, red mud and tungsten carbide Brunori, C et.al, [15]. The results are shown that the addition of tungsten carbide particles to the pure aluminium with micro level and nano level red mud tremendously increased the wear resistance of hybrid metal matrix composite.

7.2 LIMITATION OF THIS WORK

- The current study is limited to the compacting pressure of 40 bar, it can be further be increased.

7.3 SCOPE FOR THE FUTURE WORK

- In this study, the tribological characterization of heat treatment samples with air cooling is done. The work can be further extended to other quenching media like water, oil quenching, brine solution etc at different soaking times for good wear resistant properties.
- The present investigation is limited to conventional sintering through powder metallurgy only. However, other available advanced techniques like Spark Plasma Sintering etc could be tried.
- The present investigation is limited to sintering with vacuum as medium. However, other inert gases will also be used for preparation of powder metallurgy samples.
- The present work can also be extended to study various sintering parameters.

APPENDIX - I

INTRODUCTION

The Appendix-I consists of compressive stresses for pure aluminium, pure aluminium with 2% and 4% weight fractions of 100 μm , 150 μm , 200 μm and 42 nm particle size red mud at 10%, 20% and 30% reduction using Deform-2D software. This Appendix-I also consists of compressive stresses for pure aluminium with 6% weight fractions of 100 μm , 150 μm and 200 μm particle size red mud at 10%, 20% and 30% reduction using Deform-2D software. The compressive stress for pure aluminium with 6% weight fraction of 42 nm red mud at 10%, 20%, and 30% reduction using Deform-2D software are shown in Chapter-4 (Figure 4.14-4.16).

The compressive stress for pure aluminium at 10% reduction and 20% reduction using Deform-2D software are shown in Figure 1 and 2 respectively.

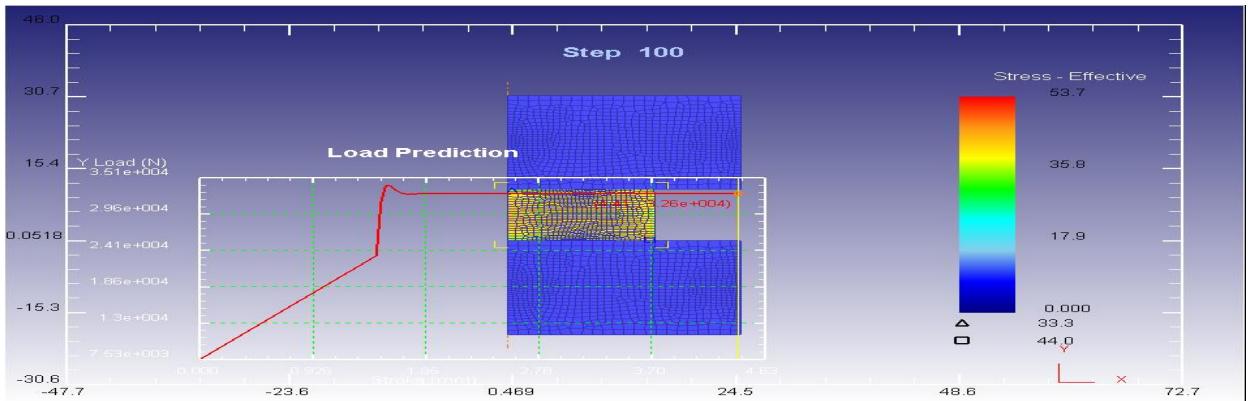

Figure 1: Compressive Stress for pure aluminium at 10% reduction using Deform-2D software

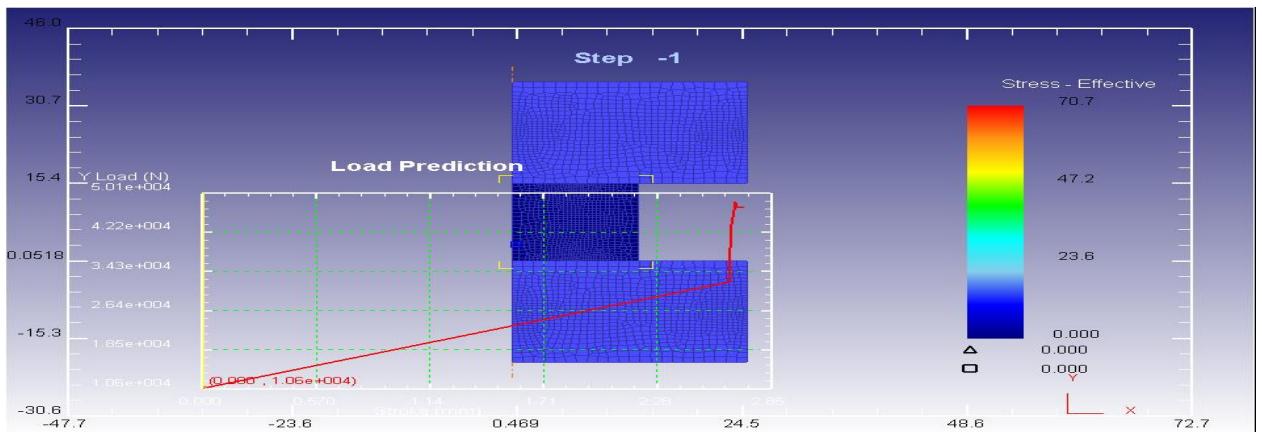

Figure 2: Compressive Stress for pure aluminium at 20% reduction using Deform-2D software

The compressive stress for pure aluminium at 30% reduction using Deform-2D software is shown in Figure 3.

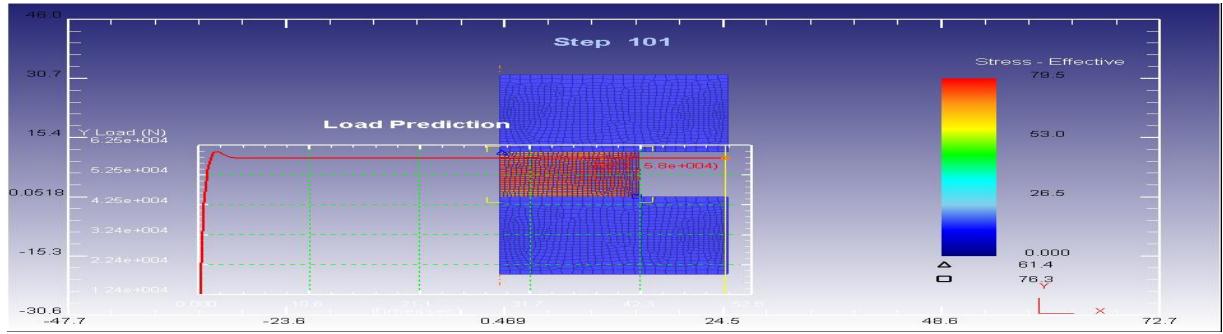

Figure 3: Compressive Stress for pure aluminium at 30% reduction using Deform-2D software

The compressive stress for pure aluminium with 2% weight fraction of red mud (100 μm) at 10% reduction and 20% reduction using Deform-2D software are shown in Figure 4 and 5 respectively.

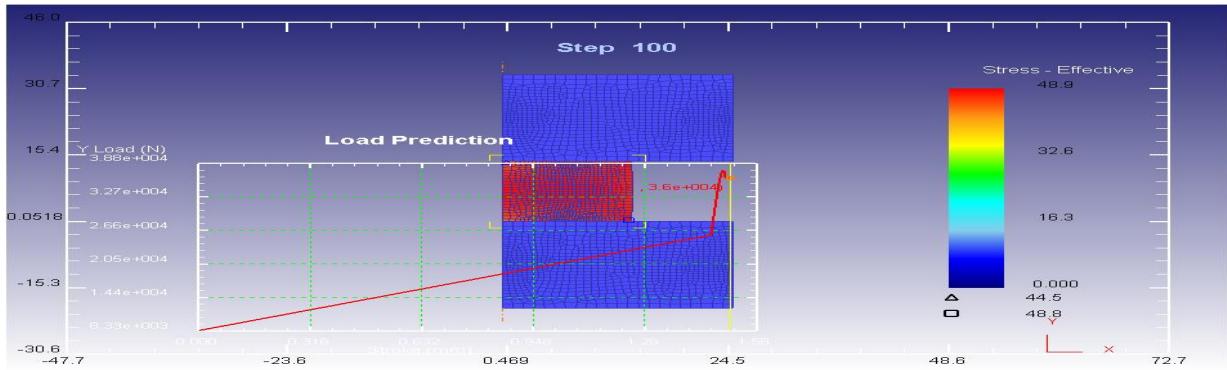

Figure 4: Compressive Stress for aluminium with 2% weight fraction of red mud (100 μm) at 10% reduction using Deform-2D software

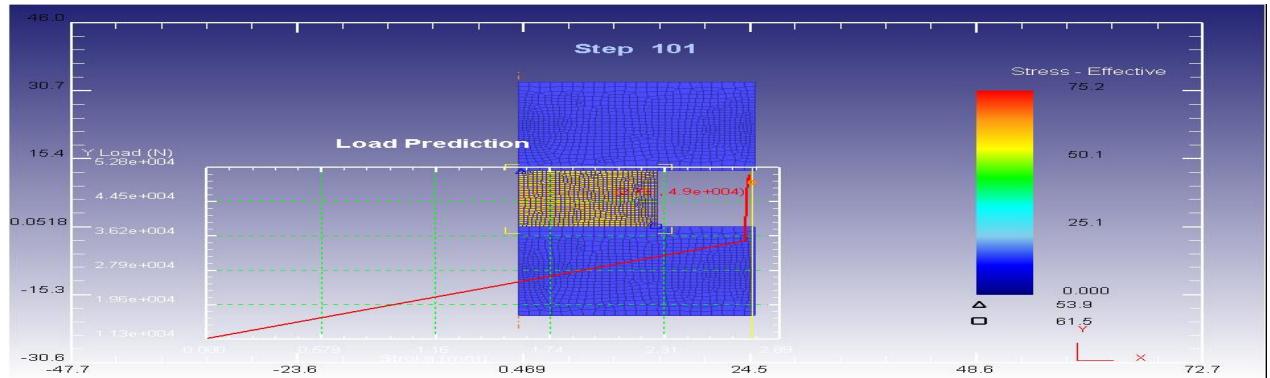

Figure 5: Compressive Stress for aluminium with 2% weight fraction of red mud (100 μm) at 20% reduction using Deform-2D software

The compressive stress for pure aluminium with 2% weight fraction of red mud (100 μm) at 30% reduction using Deform-2D software is shown in Figure 6.

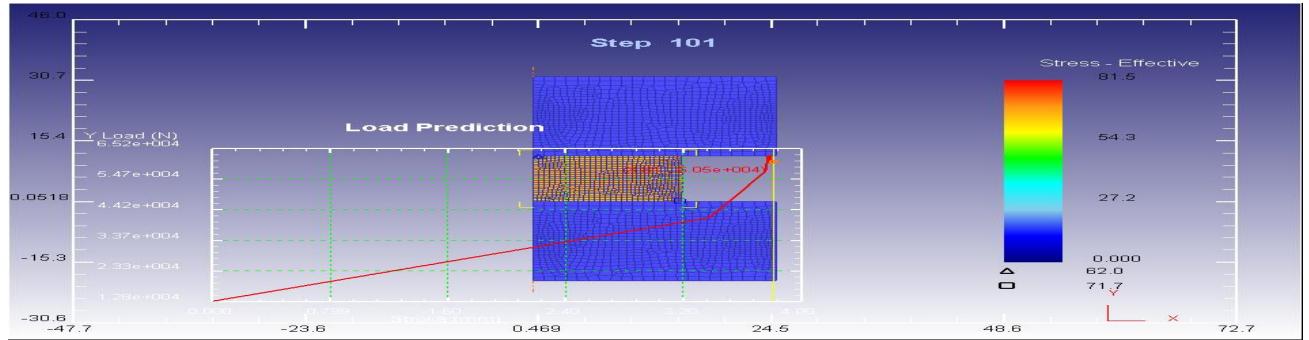

Figure 6: Compressive Stress for aluminium with 2% weight fraction of red mud (100 μm) at 30% reduction using Deform-2D software

The compressive stress for pure aluminium with 2% weight fraction of red mud (150 μm) at 10% reduction and 20% reduction using Deform-2D software are shown in Figure 7 and 8 respectively.

CONCLUSION

The present Appendix-I gives the Deform-2D Compressive stress simulation results for pure aluminium, pure aluminium with 2 % and 4 % weight fractions of 100 μ m, 150 μ m, 200 μ m and 42 nm particle size red mud at 10%, 20% and 30% reduction. The compressive stress for pure aluminium with 6% weight fraction of 42 nm red mud at 10%, 20%, and 30% reduction using Deform-2D software are shown in Chapter-4 (Figure 4.14-4.16). The compressive stresses for pure aluminium with 6% weight fractions of 150 μ m and 200 μ m particle size red mud at 10%, 20% and 30% reduction figures using Deform-2D software are removed due to lengthy appendix. This Appendix-I also consists of compressive stresses for pure aluminium with 6% weight fractions of 100 μ m particle size red mud at 10%, 20% and 30% reduction using Deform-2D software.

APPENDIX - II

INTRODUCTION

The Appendix-II consists of Appendix-II-A and Appendix-II-B parts. The Appendix-II-A consists of wear rate tables for pure aluminium with red mud of 10 N, 20 N and 30 N loads at normal condition. The Appendix-II-B consists of wear rate tables for pure aluminium with red mud of 10 N, 20 N and 30 N loads at heat treatment conditions. The various graphs between wear rate, percentage weight fraction of red mud, particle size of red mud at normal and heat treatment conditions are shown in Chapter-5 (Figure 5.2- 5.19)

APPENDIX II-A

i) Wear rate tables for pure aluminium with red mud at normal condition at 10 N load

The Wear rate values for pure aluminium at 200 rpm and 400 rpm are shown in Tables 1 and 2 respectively.

m_1 = Initial mass, gm; m_2 = Final mass, gm; Δm = Initial mass – Final mass, gm;

t = Time, sec; F_f = Average frictional force, kgf;

μ = Co-efficient of friction;

$R.D$ = Rolling / Sliding distance, m;

W_r = Wear rate, N/m;

W_v = Volumetric Wear rate, m^3/sec ; W_s = Specific Wear rate, $m^3/N\cdot m$

Table 2: Wear Rate values for Pure Aluminium at 400 rpm

$V_s = 8.35 \times 10^{-1} \text{ m/sec}$

CONCLUSION

The present Appendix-II gives the wear rate tables for pure aluminium with red mud of 10 N, 20 N and 30 N loads at normal condition and heat treatment conditions in two parts i.e., Appendix-II-A and Appendix-II-B. In the Chapter-5, the graphs are plotted for these Appendix II wear rate tables (Figure 5.2-5.19).

APPENDIX - III

INTRODUCTION

The Appendix-III consists of Appendix-III-A and Appendix-III-B parts. The Appendix-III-A consists of wear rate tables for pure aluminium and 4% tungsten carbide with 2%, 4% and 6% red mud of 10 N, 20 N and 30 N loads at normal condition. The Appendix-III-B consists of wear rate tables for pure aluminium and 4% tungsten carbide with 2%, 4% and 6% red mud of 10 N, 20 N and 30 N loads at heat treatment conditions. In Chapter-6 (Figure 6.1-6.9), the graphs are plotted for these Appendix III wear rate tables.

APPENDIX III - A (AT NORMAL CONDITION)

i) Wear rate tables for pure aluminium with red mud and 4% tungsten carbide at 10N load

The Wear rate value for pure aluminium with 4% tungsten carbide and 2% red mud of 100 μm particle size at 600 rpm is shown in Table 1.

Table 1: Wear rate values for pure aluminium with 4% tungsten carbide and 2% red mud of 100 μm particle size at 600 rpm

CONCLUSION

The present Appendix-III gives the wear rate tables for pure aluminium with 2%, 4% and 6% red mud and 4% tungsten carbide of 10 N, 20 N and 30 N loads at normal condition and heat treatment conditions in two parts i.e., Appendix-III-A and Appendix-III-B. In the Chapter-6, the graphs are plotted for these Appendix III wear rate tables (Figure 6.1-6.9).

BIO-DATA

Name	NEELIMA DEVI CHINTA
Date of Birth	18-08-1982
Marital Status	Married
Present Position	Assistant Professor Department of Mechanical Engineering University College of Engineering JNTUK-UCEV, Vizianagaram-535003 Andhra Pradesh, India.
Qualification	M.E. (CAD/CAM)
Permanent Address	Staff Quarters -F3, University College of Engineering JNTUK-UCEV, Vizianagaram-535003 Andhra Pradesh, India.
E-mail	cneelima.me@jntukucev.ac.in jntukneelima@gmail.com

ACKNOWLEDGEMENTS

It is beyond my capacity to express deep sense of gratitude to my Supervisor **Prof. N. Selvaraj** for his meticulous guidance, constant encouragement and moral support throughout the course of this research work. I express my sincere gratitude and thanks to my Co-Supervisor **Prof. V. Mahesh**, Principal and Professor of Mechanical Engineering Department, S.R. Engineering College, Warangal for his continuous guidance and encouragement, which lead to the successful completion of this research work. I express my sincere gratitude and heartfelt thanks to **Prof. S. Srinivasa Rao**, Chairman - DSC and Head, Mechanical Engineering Department, National Institute of Technology, Warangal for his valuable guidance and suggestions during the research work.

I express my sincere thanks to **Director**, National Institute of Technology, Warangal for providing the necessary help in completing the research work at the institute. I am very much thankful to **Dr. M. J. Davidson**, Assistant Professor, Department of Mechanical Engineering, **Dr. Asith Kumar Khanra**, Assistant Professor, Department of Metallurgy and Materials Engineering and **Prof. A. R. C. Reddy**, Former Registrar NIT, Warangal and retired Professor of Physics Department, the members of DSC for giving directions and suitable suggestions during the course of study. I express my sincere gratitude and heartfelt thanks to **Prof. C. S. P. Rao**, Professor of Mechanical Engineering Department, National Institute of Technology, Warangal for his valuable guidance and suggestions during the research work

I express my sincere thanks to **all the faculty members** in Mechanical Engineering Department for their support during my research work. I express my sincere thanks to my co-scholars **T. Nagaveni, K. Kishore Kumar and P. Madhukar** for their help in completion of my research work. I wish to extend my sincere thanks to my **parents**, husband **Adepu Ashok Kumar**, only daughter **A. Ananya** and **family members**

for their understanding and continual support during the period of this research work. Finally, I thank everyone who contributed either directly or indirectly in the successful completion of this research work.

(C. Neelima Devi)
